Enright (Kiva Systems), Paolo Frasca (Roma), Anurag Ganguli (UtopiaCompression), João P. Hespanha (UCSB) Sonia Martínez (UCSD), Karl Obermeyer (UCSB), and Sara Susca (Honeywell).

Autonomy and Networking Technologies

Individual members in the group can

- sense its immediate environment
- communicate with others
- process the information gathered
- take a local action in response

Dynamic Vehicle Routing (Lecture 1/8)

Prototypical Dynamic Vehicle Routing Problem

Given:

- a group of vehicles, and
- a set of service demands

Objective:

provide service in minimum time service = take a picture at location

Vehicle routing

(All info known ahead of time, Dantzig '59)

Determine a set of paths that allow vehicles to service the demands

Dynamic vehicle routing

(New info in real time, Psaraftis '88)

- New demands arise in real-time
- Existing demands evolve over time

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 1/8)

Lecture outline

- Literature review
- - Re-optimization
 - Online algorithms

Light and heavy load regimes

Dynamic Vehicle Routing (Lecture 1/8)

From coordination and static routing to Dynamic Vehicle Routing

Simple coordination problems arise in static environments

- 1 motion coordination: rendezvous, deployment, flocking
- 2 task allocation, target assignment
- static vehicle routing

(P. Toth and D. Vigo '01)

Routing policies vs planning algorithms

dynamic, stochastic and adversarial events take place

- 1 design policies (in contrast to pre-planned routes or motion planning algorithms) to specify how to react to events
- ② dynamic demands add queueing phenomena to the combinatorial nature of vehicle routing

Literature on DVR and queueing for robotic networks

- Shortest path through randomly-generated and worst-case points (Beardwood, Halton and Hammersly, 1959 — Steele, 1990)
- Traveling salesman problem solvers

(Lin, Kernighan, 1973)

DVR formulation on a graph

(Psaraftis, 1988)

DVR on Euclidean plane

(Bertsimas and Van Ryzin, 1990–1993)

Unified receding-horizon policy

(Papastavrou, 1996)

Recent developments in DVR for robotic networks:

- Adaptation and decentralization
- Vehicles with dynamics, nonholonomic vehicles, Dubins UAVs
- Pickup & delivery tasks
- Heterogeneous vehicles and team forming
- Distinct-priority and impatient demands
- Moving demands

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 1/8) 29jun10 @ Baltimore, ACC

Contributions of our recent works

Comprehensive framework for DVR in robotic systems

- 1 adaptive DVR policies for single vehicles in light and heavy load
- 2 cooperative DVR policies via partitioning
- scalable distributed partitioning policies under a variety of communication/interaction scenarios
- (models, algorithms and analysis of) service vehicles with dynamics & stochastic and combinatorics of nonholonomic Dubins vehicles performing Traveling Salesman Problems and DVR tasks
- (models, algorithms and analysis of) service vehicles with time constraints and heterogeneous priorities
- (models, algorithms and analysis of) demands requiring service by multiple heterogeneous vehicles simultaneously.

- For adversarial target generation, vehicle travels forever without ever servicing any request \implies unstable queue of outstanding requests
- 2 Even if queue remains bounded, what about performance? how far from the optimal?

Online algorithms?

Online algorithms

(Jaillet and M. R. Wagner '06)

- online algorithm operates based on input information up to the current time
- online algorithm is (worst-case) r-competitive if

 $Cost_{online}(I) \leq rCost_{optimal\ offline}(I)$, \forall problem instances I.

Disadvantages

- cumulative cost
- worst-case analysis
- on not possible to include a-priori information (e.g., arrival rate)
- onot as clear what competitive ratio means
- 5 so far, only few simple DVR problems admit online algorithms

Dynamic Vehicle Routing (Lecture 2/8)

Metric if

Euclidean if

Minimum Spanning Tree

- A tree is a graph with no cycles
- A spanning tree of G is a subgraph that
 - is a tree
 - 2 connects all vertices together

Minimum Spanning Tree Problem

Given: a weighted graph G - (V, E, c)

Task: find a spanning tree $T = (E_T, V_T)$ such that $\sum_{e \in E_T} c(e)$ is minimum.

Can be solved in greedy fashion using Kruskal's algorithm:

- Recursively adds shortest edge that does not create a cycle
- Runs in $O(n^2)$ time (where |V| = n)

Weighted Graphs

• In a complete graph, $E = V \times V$.

Special classes of complete weighted graphs:

Dynamic Vehicle Routing (Lecture 2/8)

- Similarly define a Hamiltonian cycle or tour.

Dynamic Vehicle Routing (Lecture 2/8)

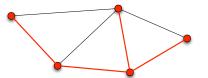

• A weighted graph G = (V, E, c) has edge weights $c : E \to \mathbb{R}_{>0}$.

 $c(\{v_1, v_2\}) + c(\{v_2, v_3\}) > c(\{v_1, v_3\})$ for all $v_1, v_2, v_3 \in V$.

 $V \subset \mathbb{R}^d$ and $c(\lbrace v_i, v_i \rbrace) = ||v_i - v_i||_2$.

Minimum Spanning Tree

- A tree is a graph with no cycles
- A spanning tree of G is a subgraph that
 - is a tree
 - connects all vertices together

Minimum Spanning Tree Problem

Given: a weighted graph G - (V, E, c)

Task: find a spanning tree $T = (E_T, V_T)$ such that $\sum_{e \in E_T} c(e)$ is minimum.

Can be solved in greedy fashion using Kruskal's algorithm:

- Recursively adds shortest edge that does not create a cycle
- Runs in $O(n^2)$ time (where |V| = n)

Hamiltonian Cycle Decision Problem

Hamiltonian Cycle

Given: An undirected graph G.

Question: Does G contain a Hamiltonian cycle?

Hamiltonian Cycle is NP-complete

(One of Karp's 21 NP-complete problems)

Recall, a problem is NP-complete if

- Every solution can be verified in polynomial time (NP).
- Every problem in NP can be reduced to it.

Dynamic Vehicle Routing (Lecture 2/8)

Traveling Salesman Problem

Traveling Salesman Problem (TSP)

Given: A complete graph $G_n = (V_n, E_n)$ and weights $c : E_n \to \mathbb{R}_{>0}$.

Task: Find a Hamiltonian cycle with minimum weight.

- TSP is NP-hard
- To show NP-hard: Reduce Hamiltonian Cycle to TSP.

Given an undirected graph G = (V, E) with |V| = n:

- Construct complete graph G_n with weight 1 for each edge in E and weight 2 for all other edges.
- ② Then G is Hamiltonian \Leftrightarrow optimum TSP tour has length n.

Outline

- 2 The Traveling Salesman Problem
 - Approximation Algorithms
 - Metric TSP
 - Euclidean TSP

Approximation Algorithms for the TSP

Theorem (Sahni and Gonzalez, 1976)

Unless P = NP, there is no k-factor approx alg for the TSP for any k > 1.

Proof Idea: k-factor approx would imply poly time algorithm for Hamiltonian Cycle.

In practice for metric and non-metric problems:

- Heuristic: Lin-Kernighan based solvers (Lin and Kernighan, 1973)
 - Empirically $\sim 5\%$ of optimal in $O(n^{2.2})$ time.
- Exact: Concorde TSP Solver (Applegate, Bixby, Chvatal, Cook, 2007)
 - Exact solution of Euclidean TSP on 85,900 points!

Metric TSP

Metric TSP

Given: A complete metric graph $G_n = (V_n, E_n)$

Task: Find a Hamiltonian cycle with minimum weight.

- The Metric TSP is NP-hard.
- There exist approximation algorithms!

Dynamic Vehicle Routing (Lecture 2/8)

Double-Tree Algorithm

Double-Tree Algorithm

of vertex.

Dynamic Vehicle Routing (Lecture 2/8)

2: $\overline{G} := \text{graph containing two copies of each edge in } T$.

4: Walk gives ordering, ignore all but first occurrence

1: Find a minimum spanning tree T of graph G_n .

3: Compute Eulerian walk in Eulerian graph \overline{G} .

Double-Tree Algorithm

Double-Tree Algorithm

- 1: Find a minimum spanning tree T of graph G_n .
- 2: $\overline{G} := \text{graph containing two copies of each edge in } T$.
- 3: Compute Eulerian walk in Eulerian graph \overline{G} .
- 4: Walk gives ordering, ignore all but first occurrence of vertex.

Eulerian Graphs

• Eulerian graph: degree of each vertex is even

Graph has Eulerian walk ⇔ Eulerian.

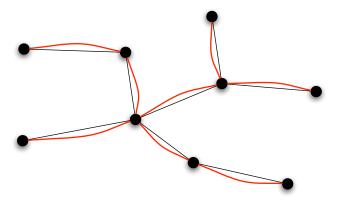

• Eulerian walk: Closed walk containing every edge.

• Eulerian walk can be computed in O(|V| + |E|) time.

Double-Tree Algorithm

Double-Tree Algorithm

- 1: Find a minimum spanning tree T of graph G_n .
- 2: \overline{G} := graph containing two copies of each edge in T.
- 3: Compute Eulerian walk in Eulerian graph \overline{G} .
- 4: Walk gives ordering, ignore all but first occurrence of vertex.

Dynamic Vehicle Routing (Lecture 2/8)

Theorem

Double-Tree Algorithm is a 2-approx algorithm for the Metric TSP. Its running time is $O(n^2)$.

- Deleting one edge from a tour gives a spanning tree.
- Thus minimum spanning tree is shorter than optimal tour.
- Each edge is doubled.

Double-Tree Algorithm

- Spanning tree can be computed in $O(n^2)$ time.
- Eulerian walk computed in O(n) time.

Christofides' Algorithm

Theorem

Christofides' Algorithm gives a 3/2-approx algorithm for the Metric TSP. Its running time is $O(n^3)$.

- L(Christofides) = L(MST) + L(M).
- But, L(MST) < L(TSP), and
- $L(M) \le L(M') \le L(\mathsf{TSP})/2$. Where M' is the minimum perfect matching of W using edges that are part of TSP.

Length Bounds for Euclidean TSP

How long is the TSP tour through n points in unit square?

Theorem (Few, 1955)

For every set Q_n of n points in the unit square

$$\mathsf{ETSP}(Q_n) \leq \sqrt{2n} + 7/4.$$

Worst-case lower bound matches:

- Equally space *n* points on a grid
- Then ETSP(Q_n) = $C\sqrt{n}$.
- So, worst-case length $\geq C\sqrt{n}$.

Euclidean TSP

Theorem (Arora, 1998; Mitchell, 1999)

For each fixed $\epsilon > 0$, a $(1 + \epsilon)$ -approximate solution can be found in $O(n^3(\log n)^c)$ time.

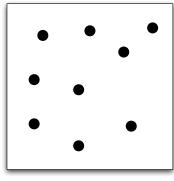

Practical value limited to due c's dependence on ϵ .

Worst-case TSP Length Upper Bound (Intuition)

- Consider $Q_n := \{x_1, \dots, x_n\}$ of n points in unit square.
- There exists c > 0 such that

$$\min\left\{\|x_i-x_j\|:x_i,x_j\in Q_n\right\}\leq \frac{c}{\sqrt{n}}.$$

- Let ℓ_n denote worst-case TSP length through n pts.
- Then $\ell_n \leq \ell_{n-1} + 2c/\sqrt{n}$.
- Summing we get $\ell(n) \leq C\sqrt{n}$.

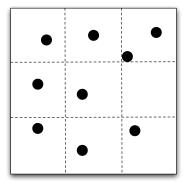

Worst-case TSP Length Upper Bound (Intuition)

- Consider $Q_n := \{x_1, \dots, x_n\}$ of *n* points in unit square.
- There exists c > 0 such that

$$\min\left\{\|x_i-x_j\|:x_i,x_j\in Q_n\right\}\leq \frac{c}{\sqrt{n}}.$$

- Let ℓ_n denote worst-case TSP length through n pts.
- Then $\ell_n \leq \ell_{n-1} + 2c/\sqrt{n}$.
- Summing we get $\ell(n) \leq C\sqrt{n}$.

TSP Length for Random Points

Theorem (Beardwood, Halton, and Hammersley, 1959)

Let Q_n be a set of n i.i.d. random variables with compact support in \mathbb{R}^d and distribution $\varphi(x)$. Then, with prob. 1

$$\lim_{n\to+\infty}\frac{\mathsf{ETSP}(Q_n)}{n^{(d-1)/d}}=\beta_{\mathsf{TSP},d}\int_{\mathbb{R}^d}\bar{\varphi}(x)^{(d-1)/d}dx,$$

where $\beta_{\mathsf{TSP},d}$ is a constant independent of φ , and $\bar{\varphi}$ is absolutely continuous part of φ .

For uniform distribution in square of area A

$$\frac{\mathsf{ETSP}(Q_n)}{\sqrt{n}} \to \beta_{\mathsf{TSP},2} \sqrt{A} \quad \text{as } n \to +\infty.$$

Best estimate of $\beta_{TSP,2}$ is Percus and Martin, 1996

$$\beta_{\mathsf{TSP},2} \simeq 0.7120.$$

Dynamic Vehicle Routing (Lecture 2/8) 29jun10 @ Baltimore, ACC

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 2/8)

Outline

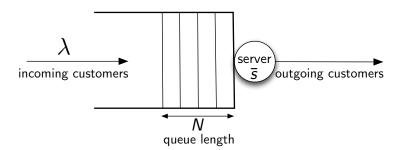

- Queueing Theory
 - Kendall's Notation
 - Little's Law and Load Factor

Summary of Traveling Salesman Problem

- Solving TSP is NP-hard, and no approx algorithms exist.
- For metric TSP, still NP-hard but good approx algs exist.
- For Euclidean TSP, very good heuristics exist.
- Length of tour through *n* points in unit square:
 - Worst-case is $\Theta(\sqrt{n})$.
 - Uniform random is $\Theta(\sqrt{n})$.
 - For all density functions $O(\sqrt{n})$.

Basic Queueing Model

- Customers arrive, wait in a queue, and are then processed
- Queue length builds up when arrival rate is larger than service rate

- Arrivals modeled as stochastic process with rate λ
- Service time of each customer is a r.v. with finite mean \bar{s} and second moment s^2 .
- Service rate is $1/\bar{s}$.

Queueing Notation

Kendall's Queueing notation A/B/C:

- \bullet A = the arrival process
- B = the service time distribution
- C = the number of servers

Main codes:

- D = Deterministic
- M = Markovian
 - for arrivals: Poisson process
 - for service times: Exponential distribution
- G (or GI) = General distribution (independent among customers)

Example M/G/m queue:

- Poisson arrivals with rate λ
- General service times with mean \bar{s}
- m servers

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 2/8) 29jun10 @ Baltimore, ACC

Wait-time examples

For M/D/1 queue:

$$\overline{W} = rac{arrho \overline{s}}{2(1-arrho)}$$

For M/G/1 queue:

$$\overline{W} = \frac{\lambda \overline{s^2}}{2(1-\rho)}$$

For G/G/1 queue (Kingman, 1962):

$$\overline{W} \le \frac{\lambda(\sigma_a^2 + \sigma_s^2)}{2(1-\rho)}$$

and the upper bound becomes exact as $\rho \to 1^-$.

Little's Law and Load Factor

Define:

- ullet average wait-time in queue as \overline{W}
- average system as $\overline{T} := \overline{W} + \overline{s}$.

Little's Law/Theorem

For a stable queue $\overline{N} = \lambda \overline{W}$

• For *m* servers, define load factor as

$$\varrho := \frac{\lambda \overline{s}}{m}$$

• Necessary condition for stable queue is $\rho < 1$.

Euclidean plane. Operations Research, 39:601-615, 1991

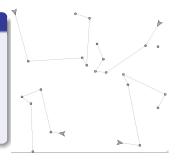

Arrival process: spatio-temporal Poisson

29jun10 @ Baltimore, ACC

The problem

DVR - distinct features

- service demands vary over time
- information about future is stochastic
- real-time routing policies
- queueing phenomena

DVR is fundamentally a queueing problem:

- arrival process
- service model
- performance measure

Lecture outline

Queueing-theoretical model for DVR

Dynamic Vehicle Routing (Lecture 3/8)

General queueing-theoretical model for DVR 1/2

Arrival process: spatio-temporal Poisson

- time intensity $\lambda > 0$
- ② spatial density φ : $\mathbb{P}[\text{demand in } S] = \int_{S} \varphi(x) dx$
- inter-arrival times and locations are i.i.d.

Service model:

- 1 m holonomic vehicles with maximum velocity v
- 2 vehicles provide a random on-site service
- on-site service times are i.i.d. (equal on average to \bar{s})
- demand removed from the system upon on-site service completion

Problem statement

Dynamic Vehicle Routing (Lecture 3/8)

inf \overline{T}_{π}

General queueing-theoretical model for DVR 2/2

Performance measure: steady-state system time of demands \overline{T}

Solve optimization problem over all causal routing policies π :

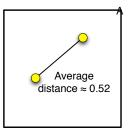

29jun10 @ Baltimore, ACC

Relation to standard queueing systems

- DVR model close to M/G/m queue
- key difference: service times are not i.i.d. in general

Service time correlations in DVR:

- service time = travel time + on-site service
- FCFS policy
- unconditional expected travel time between two consecutive demands ≈ 0.52 .
- conditional expected travel time between

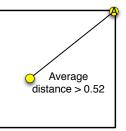

Relation to standard queueing systems

- DVR model close to M/G/m queue
- key difference: service times are not i.i.d. in general

Service time correlations in DVR:

- service time = travel time + on-site service
- FCFS policy
- unconditional expected travel time between two consecutive demands ≈ 0.52 .
- conditional expected travel time between two consecutive demands > 0.52.

M/G/m methodology is not applicable!

A first look at the problem: stability

• $\lambda \cdot \mathbb{E}[\text{service time}]/m$ fraction of time each vehicle is busy

Necessary condition for stability:

System is stable if $\lambda \cdot \mathbb{E}[\text{service time}]/m < 1$.

Since $\bar{s} \leq \mathbb{E}[\text{service time}]$, a weaker necessary condition is:

$$\varrho = \lambda \bar{s}/m < 1$$

Sufficient condition for stability:

Surprisingly, $\varrho < 1$ is also sufficient for stability \implies stability condition is independent of the size and shape of $\mathcal Q$

Analysis approach

- Lack of i.i.d. property substantially complicates analysis
- General approach:
 - 1 lower bounds on performance, independent of algorithms,
 - ② design of algorithms and upper bound on their performance, possibly in asymptotic regimes (i.e., $\rho \to 0^+$ and $\rho \to 1^-$)

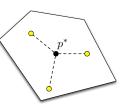

Light-load lower bound

Median

• minimizer p^* of

$$p \mapsto \int_{\mathcal{Q}} \|x - p\| \varphi(x) dx = \mathbb{E}_{\varphi}[\|X - p\|]$$

• best a priori location to reach next demand

Lower bound (most useful when $\lambda ightarrow 0^+)$

For all policies π : $\overline{T}_{\pi} \geq \mathbb{E}_{\varphi}[\|X - p^*\|]/v + \overline{s}$

Proof sketch

•
$$\overline{T} = \overline{W}_{\text{travel}} + \overline{W}_{\text{on-site}} + \overline{s}$$

•
$$\overline{W}_{\mathsf{travel}} \geq \mathbb{E}_{\varphi}[\|X - p^*\|]/v$$

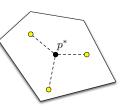

Light-load lower bound

Median

• minimizer p^* of

$$p \mapsto \int_{\mathcal{Q}} \|x - p\| \varphi(x) dx = \mathbb{E}_{\varphi}[\|X - p\|]$$

best a priori location to reach next demand

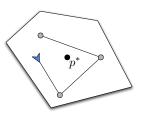

Lower bound (most useful when $\lambda \to 0^+$)

For all policies π : $\overline{T}_{\pi} \geq \mathbb{E}_{\omega}[\|X - p^*\|]/v + \overline{s}$

Proof sketch:

- $\overline{T} = \overline{W}_{\text{travel}} + \overline{W}_{\text{on site}} + \overline{5}$
- $\overline{W}_{\text{travel}} \geq \mathbb{E}_{\omega}[\|X p^*\|]/v$

Dynamic Vehicle Routing (Lecture 3/8) 29jun10 @ Baltimore, ACC

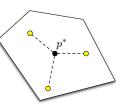

Light-load lower bound

Median

• minimizer p^* of

$$p \mapsto \int_{\mathcal{Q}} \|x - p\| \varphi(x) dx = \mathbb{E}_{\varphi}[\|X - p\|]$$

best a priori location to reach next demand

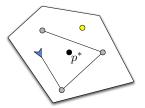

Lower bound (most useful when $\lambda o 0^+)$

For all policies π : $\overline{T}_{\pi} \geq \mathbb{E}_{\omega}[\|X - p^*\|]/v + \overline{s}$

Proof sketch:

- $\overline{T} = \overline{W}_{\text{travel}} + \overline{W}_{\text{on site}} + \overline{5}$
- $\overline{W}_{\text{travel}} \geq \mathbb{E}_{\omega}[\|X p^*\|]/v$

Dynamic Vehicle Routing (Lecture 3/8) 29jun10 @ Baltimore, ACC

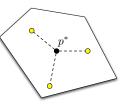

Light-load lower bound

Median

minimizer p* of

$$p \mapsto \int_{\mathcal{Q}} \|x - p\| \varphi(x) dx = \mathbb{E}_{\varphi}[\|X - p\|]$$

best a priori location to reach next demand

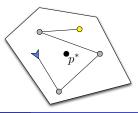

Lower bound (most useful when $\lambda \to 0^+$)

For all policies π : $\overline{T}_{\pi} \geq \mathbb{E}_{\varphi}[\|X - p^*\|]/v + \overline{s}$

Proof sketch:

- $\overline{T} = \overline{W}_{\text{travel}} + \overline{W}_{\text{on-site}} + \overline{s}$
- $\overline{W}_{\text{travel}} > \mathbb{E}_{\omega}[\|X p^*\|]/v$

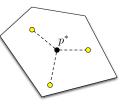

Light-load lower bound

Median

• minimizer p^* of

$$p \mapsto \int_{\mathcal{Q}} \|x - p\| \varphi(x) dx = \mathbb{E}_{\varphi}[\|X - p\|]$$

• best a priori location to reach next demand

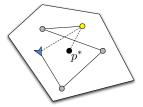

Lower bound (most useful when $\lambda ightarrow 0^+$)

For all policies π : $\overline{T}_{\pi} \geq \mathbb{E}_{\omega}[\|X - p^*\|]/v + \bar{s}$

Proof sketch:

- $\overline{T} = \overline{W}_{\text{travel}} + \overline{W}_{\text{on-site}} + \overline{s}$
- $\overline{W}_{\text{travel}} > \mathbb{E}_{\omega}[\|X p^*\|]/v$

Heavy-load lower bound

Definition (Spatially-biased and -unbiased policies)

A policy π is said to be

- spatially unbiased if system time is independent of demand location
- spatially biased if system time depends on demand location

spatially-unbiased policies:
$$\overline{T}_{\pi} \geq \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda \, \left(\int_{\mathcal{Q}} \varphi^{1/2}(x) dx \right)^2}{v^2 \, (1-\varrho)^2} \quad \text{as } \varrho \to 1^-$$
 spatially-biased policies: $\overline{T}_{\pi} \geq \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda \, \left(\int_{\mathcal{Q}} \varphi^{2/3}(x) dx \right)^3}{v^2 \, (1-\varrho)^2} \quad \text{as } \varrho \to 1^-$

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 3/8) 29jun10 @ Baltimore, ACC

FB, EF, MP, KS, SLS (UCSB, MIT)

Proof sketch (for unbiased policies)

Proof of the lower bound:

- the idea is to use stability arguments (which are independent of policies!)
- let \overline{D} be the travel inter-demand distance
- one can show that

$$\overline{D} \ge \beta_{\mathrm{TSP}} \, \frac{\int_{\mathcal{Q}} \varphi^{1/2}(x) dx}{\sqrt{2 \, \overline{N}}} \qquad \text{as } \varrho \to 1^-,$$

with \overline{N} average number of waiting demands

for stability:

$$\bar{s} + \frac{\overline{D}}{v} \le \frac{1}{\lambda} \implies \bar{s} + \beta_{\mathrm{TSP}} \frac{\int_{\mathcal{Q}} \varphi^{1/2}(x) dx}{v \sqrt{2 \, \overline{N}}} \le 1/\lambda$$

• since $\overline{N} = \lambda \overline{W}$ and $\overline{T} = \overline{W} + \overline{s}$ one obtains:

$$\overline{T}^* \geq rac{eta_{ ext{TSP}}^2}{2} \, rac{\lambda \, \left(\int_{\mathcal{Q}} arphi^{1/2}(x) dx
ight)^2}{v^2 \, (1-arrho)^2}$$

Heavy-load lower bound

Definition (Spatially-biased and -unbiased policies)

A policy π is said to be

- spatially unbiased if system time is independent of demand location
- 2 spatially biased if system time depends on demand location

Heavy-load lower bound

$$\text{spatially-unbiased policies: } \overline{T}_{\pi} \geq \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda \, \left(\int_{\mathcal{Q}} \varphi^{1/2}(x) dx \right)^2}{v^2 \, (1-\varrho)^2} \quad \text{as } \varrho \to 1^-$$

spatially-biased policies:
$$\overline{T}_{\pi} \geq \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda \, \left(\int_{\mathcal{Q}} \varphi^{2/3}(x) dx\right)^3}{v^2 \, (1-\varrho)^2}$$
 as $\varrho \to 1^-$

An optimal light load policy

Stochastic Queueing Median (SQM)

Compute median p^* . Then:

- 1: service demands in FCFS order
- 2: return to p^* after each service is completed

Optimality of SQM policy

$$\lim_{\lambda \to 0^+} \overline{T}_{\mathsf{SQM}}/\overline{T}^* = 1$$

- As $\lambda \to 0^+$, \mathbb{P} [demand generated when system is empty] $\to 1$
- \Rightarrow all demands generated with the vehicle at p^*
- $\bullet \Rightarrow \overline{T}_{SOM} = \mathbb{E}_{\emptyset}[\|X p^*\|]/v + \overline{s}$

Dynamic Vehicle Routing (Lecture 3/8)

An optimal light load policy

Stochastic Queueing Median (SQM)

Compute median p^* . Then:

- 1: service demands in FCFS order
- 2: return to p^* after each service is completed

Optimality of SQM policy

$$\lim_{\lambda o 0^+} \overline{T}_{\mathsf{SQM}}/\overline{T}^* = 1$$

Proof sketch

- As $\lambda \to 0^+$, \mathbb{P} [demand generated when system is empty] $\to 1$
- \Rightarrow all demands generated with the vehicle at p^*
- $\bullet \Rightarrow \overline{T}_{SOM} = \mathbb{E}_{\varphi}[\|X p^*\|]/v + \overline{s}$

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 3/8) 29jun10 @ Baltimore, ACC

An optimal spatially-unbiased heavy-load policy

Unbiased TSP (UTSP)

Partition Q into r subregions Q_k with $\int_{Q_k} \varphi(x) dx = 1/r$. Then:

- 1: within each subregion form sets of size n/r
- 2: deposit sets in a queue
- 3: service sets FCFS by following a TSP tour

Optimize over *n*.

Optimality of UTSP policy

$$\lim_{\rho \to 1^-} \overline{T}_{\mathsf{UTSP}}(r) / \overline{T}_{\mathsf{U}}^* \leq 1 + 1/r$$

Proof

Proof (r=1)

- idea: reduction to GI/G/1 queue
- jth set viewed as jth customer: arrival and service times are i.i.d.!
- inter-arrival distribution is Erlang of order n
- expected service time is $n\bar{s} + \beta_{TSP} \sqrt{n} \int_{\mathcal{O}} \varphi^{1/2}(x) dx/v$
- standard results give upper bound on the wait in queue for a set
- then easy to find upper bound for individual demands

Comments

Relation with non-spatial queueing systems:

- wait time grows as $(1-\rho)^{-2}$ instead of $(1-\rho)^{-1}$!
- DVR problems are fundamentally different from traditional queueing systems (techniques, results, etc.)

Analysis techniques:

- for light load: locational optimization
- for heavy load: reduction to classic queueing systems or control-theoretical methods

Biased/unbiased:

 biased service provides strict reduction of optimal system time for any non-uniform φ

Dynamic Vehicle Routing (Lecture 3/8) 29jun10 @ Baltimore, ACC

Adaptivity

SQM policy not adaptive:

- SQM unstable as $\rho \to 1^-$
- intuition: average per-demand travel \overline{D} is fixed
- but stability condition implies $\overline{D} < (1 \rho)/\lambda!$

UTSP and **BTSP** policies not adaptive:

• for stability of the queue of sets:

$$\frac{\lambda}{n}\Big(n\,\overline{s}+eta_{\mathrm{TSP}}\,\sqrt{n}\,\int_{\mathcal{Q}}\varphi^{1/2}(x)dx/v\Big)<1$$

• then one should a priori select:

$$n > \lambda^2 \beta_{\mathrm{TSP}}^2 \left[\int_{\mathcal{Q}} \varphi^{1/2}(x) \, dx \right]^2 / (v^2 (1 - \varrho)^2)$$

 $\bullet \Rightarrow$ wrong selection of *n* might lead to instability or unacceptable deterioration in performance

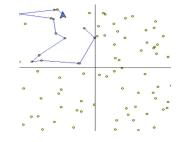

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 3/8) 29jun10 @ Baltimore, ACC

Divide & Conquer policy

Divide & Conquer (DC)

Partition Q into r subregions Q_k with $\int_{Q_k} \varphi(x) dx$ Then:

- 1: while no customers, move to empirical median \tilde{p}^*
- 2: while customers waiting
 - \bullet move to subregion Q_k
 - service all demands in Q_k by following a TSP tour

DC policy (with $r \to +\infty$)

Implementation:

NP-hard computation, but effective heuristics

Adaptation: the policy does not require knowledge of

- \bullet vehicle velocity v, environment Q
- \mathbf{Q} arrival rate λ
- \odot expected on-site service \bar{s}

Performance:

- 1 in light load, delay is optimal
- 2 in heavy load, delay is optimal
- 3 stable in any load condition

optimal and adaptive very little known outside of asymptotic regimes

Proof(r=1)

Light load:

• $\tilde{p}^* \rightarrow p^*$ and recovers SQM

Heavy load:

- no well-defined notion of "jth customer"
- focus on dynamical system

$$\mathbb{E}[n_{i+1}] \le \lambda \, \mathbb{E}\Big[\sum_{q=1}^{n_i} s_q + \mathrm{TSP}(n_i)\Big]$$
$$\le \lambda \left(\bar{s} \, \mathbb{E}[n_i] + \beta_{\mathrm{TSP}} \int_{\mathcal{O}} \varphi^{1/2}(x) dx \, \sqrt{\mathbb{E}[n_i]} / v\right)$$

• upper bound trajectories with the trajectories of virtual dynamical system

$$z_{i+1} = \varrho z_i + (\lambda/\nu) \beta_{TSP} \int_{\mathcal{Q}} \varphi^{1/2}(x) dx \sqrt{z_i}$$

• $\overline{T}_{DC} \leq \lim_{i \to +\infty} z_i / \lambda$

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 3/8) 29jun10 @ Baltimore, ACC

RH policy

Implementation:

NP-hard computation, but effective heuristics

Adaptation: the policy does not require knowledge of

- \bullet vehicle velocity v, environment Q
- 2 arrival rate λ and spatial density function φ
- \odot expected on-site service \overline{s}

Performance:

- 1 in light load, delay is optimal
- 2 in heavy load, delay is within a multiplicative factor from optimal
- 3 multiplicative factor depends upon φ and is conjectured to equal 2

adaptive to all parameters

Receding-Horizon policy

Receding-Horizon (RH)

For $\eta \in (0,1]$, single agent performs:

- 1: while no customers, move to empirical median \tilde{p}^*
- 2: while customers waiting
 - 1 compute TSP tour through current demands
 - 2 service η -fraction of path

Lecture outline

- Territory Partitioning
- 2 The multi-vehicle DVR problem
- Multi-vehicle DVR policies based on partitioning

Load balancing in DVR via territory partitioning

- Resource allocation in DVR is transcribed into partitioning!
- Focus of this lecture is mutivehicle DVR via optimal partitioning

Territory partitioning is ... art

Ocean Park Paintings, by Richard Diebenkorn (1922-1993)

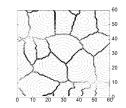

Territory partitioning: optimality and behaviors

DESIGN of performance metrics

- 4 how to design a minimum-distortion (fixed-rate) vector quantizer?

ANALYSIS of cooperative distributed behaviors

how do animals share territory? how do they decide foraging ranges?

how do they decide nest locations?

- what if each robot goes to "center" of own dominance region?
- what if each robot moves away from closest vehicle?

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 4/8)

29jun10 @ Baltimore, ACC

Multi-center functions

Expected wait time (in light load)

• n robots at $p = \{p_1, \ldots, p_n\}$

29jun10 @ Baltimore, ACC

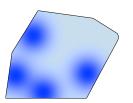

- how to cover a region with *n* minimum-radius overlapping disks?
- where to place mailboxes in a city / cache servers on the internet?

 $\mathcal{H}(p, v) = \sum_{i=1}^{n} \int_{V_i} f(\|x - p_i\|) \varphi(x) dx$

• environment is partitioned into $v = \{v_1, \dots, v_n\}$

• $f: \mathbb{R}_{\geq 0} \to \mathbb{R}$ penalty function

F. Bullo, J. Cortés, and S. Martínez. Distributed Control of Robotic Networks. Applied Mathematics Series, Princeton University Press, 2009, Available at http://www.coordinationbook.info

 $\mathcal{H}(p, v) = \int_{V_1} \|x - p_1\| dx + \cdots + \int_{V_n} \|x - p_n\| dx$

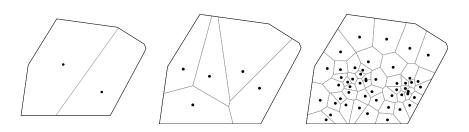

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 4/8)

Optimal partitioning

The Voronoi partition $\{V_1, \ldots, V_n\}$ generated by points (p_1, \ldots, p_n)

$$V_i(p) = \{x \in \mathcal{Q} | \|x - p_i\| \le \|x - p_j\|, \ \forall j \ne i\}$$

$$= \mathcal{Q} \bigcap_{j} (\text{half plane between } i \text{ and } j, \text{ containing } i)$$

Descartes 1644. Dirichlet 1850. Voronoi 1908. Thiessen 1911. Fortune 1986 (sweepline algorithm $O(n \log(n))$)

Optimal centering (for region ν with density φ)

function of p

minimizer = center

$$p \mapsto \int_{V} \|x - p\| \varphi(x) dx$$

median (or Fermat-Weber point)

$$p \mapsto \int_{\mathcal{X}} \|x - p\|^2 \varphi(x) dx$$

centroid (or center of mass)

$$p \mapsto \operatorname{area}(v \cap \operatorname{disk}(p, r))$$

r-area center

 $p \mapsto \text{radius of largest disk centered}$ at p enclosed inside v

 $p \mapsto \text{radius of smallest disk cen-}$ circumcenter tered at p enclosing v

How to compute the median of a convex set

For convex planar set \mathcal{Q} with strictly positive density φ ,

$$\mathcal{H}_{\mathsf{FW}}(p) = \int_{\mathcal{Q}} \|p - x\| \varphi(x) dx$$

- \bullet \mathcal{H}_{FW} is strictly convex
- the global minimum point is in Q and is called *median* of Q
- compute median via gradient flow with

$$\frac{d}{dp}\mathcal{H}_{FW}(p) = \int_{\mathcal{Q}} \frac{p-x}{\|p-x\|} \varphi(x) dx$$

Dynamic Vehicle Routing (Lecture 4/8)

Gradient algorithm for multicenter function

After assuming v is Voronoi partition,

$$\mathcal{H}(p) = \sum_{i=1}^{n} \int_{V_{j}(p)} f(\|x - p_{j}\|) \varphi(x) dx$$

For f smooth, note simplifications for boundary terms

$$\frac{\partial \mathcal{H}}{\partial p_{i}}(p) = \int_{V_{i}(p)} \frac{\partial}{\partial p_{i}} f(\|x - p_{i}\|) \varphi(x) dx$$

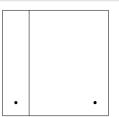

From optimality conditions to algorithms

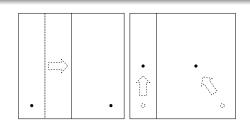

$$\mathcal{H}(p,v) = \sum_{i=1}^n \int_{v_i} f(\|x - p_i\|) \varphi(x) dx$$

Theorem (Alternating Algorithm, Lloyd '57)

- 1 at fixed positions, optimal partition is Voronoi
- 2 at fixed partition, optimal positions are "generalized centers"
- 3 alternate v-p optimization

 \implies local optimum = center Voronoi partition

Dynamic Vehicle Routing (Lecture 4/8)

Gradient algorithm for multicenter function

After assuming v is Voronoi partition,

$$\mathcal{H}(p) = \sum_{i=1}^{n} \int_{V_{j}(p)} f(\|x - p_{j}\|) \varphi(x) dx$$

For f smooth, note simplifications for boundary terms

$$\frac{\partial \mathcal{H}}{\partial p_{i}}(p) = \int_{V_{i}(p)} \frac{\partial}{\partial p_{i}} f(\|x - p_{i}\|) \varphi(x) dx + \int_{\partial V_{i}(p)} f(\|x - p_{i}\|) \langle n_{i}(x), \frac{\partial x}{\partial p_{i}} \rangle \varphi(x) dx$$

Gradient algorithm for multicenter function

After assuming v is Voronoi partition,

$$\mathcal{H}(p) = \sum_{j=1}^{n} \int_{V_{j}(p)} f(\|x - p_{j}\|) \varphi(x) dx$$

For f smooth, note simplifications for boundary terms

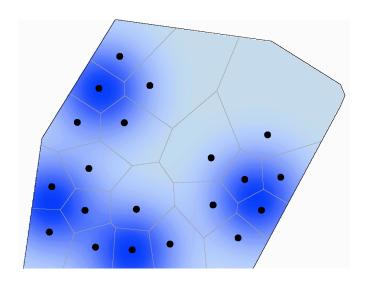

$$\frac{\partial \mathcal{H}}{\partial p_{i}}(p) = \int_{V_{i}(p)} \frac{\partial}{\partial p_{i}} f(\|x - p_{i}\|) \varphi(x) dx$$

$$+ \int_{\partial V_{i}(p)} f(\|x - p_{i}\|) \langle n_{i}(x), \frac{\partial x}{\partial p_{i}} \rangle \varphi(x) dx$$

$$+ \sum_{j \text{ neigh } i} \int_{\partial V_{j}(p) \cap \partial V_{i}(p)} f(\|x - p_{j}\|) \langle n_{ji}(x), \frac{\partial x}{\partial p_{i}} \rangle \varphi(x) dx$$
contrib from neighbors

Dynamic Vehicle Routing (Lecture 4/8) 29jun10 @ Baltimore, ACC

Example optimal partition

Gradient algorithm for multicenter function

After assuming v is Voronoi partition,

$$\mathcal{H}(p) = \sum_{j=1}^{n} \int_{V_{j}(p)} f(\|x - p_{j}\|) \varphi(x) dx$$

For f smooth, note simplifications for boundary terms

$$\frac{\partial \mathcal{H}}{\partial p_{i}}(p) = \int_{V_{i}(p)} \frac{\partial}{\partial p_{i}} f(\|x - p_{i}\|) \varphi(x) dx$$

$$+ \int_{\partial V_{i}(p)} f(\|x - p_{i}\|) \langle n_{i}(x), \frac{\partial x}{\partial p_{i}} \rangle \varphi(x) dx$$

$$- \int_{\partial V_{i}(P)} f(\|x - p_{i}\|) \langle n_{i}(x), \frac{\partial x}{\partial p_{i}} \rangle \varphi(x) dx$$

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 4/8)

Lecture outline

- 2 The multi-vehicle DVR problem

D. J. Bertsimas and G. J. van Ryzin. Stochastic and dynamic vehicle routing with general interarrival and service time distributions. Advances in Applied Probability, 25:947-978, 1993

Multi-vehicle DVR problem

- results on single-vehicle DVR generalize easily to the multi-vehicle case
- previous methodology (locational optimization, queueing and control theory, combinatorics) applicable to this case
- main new idea: partitioning

Multi - Median

• minimizer $p^* = \{p_1^*, \dots, p_m^*\}$ of

Light-load lower bound

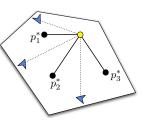

$$p \mapsto \mathbb{E}_{\varphi}[\min_{i} \|X - p_i\|] = \sum_{i=1}^{m} \int_{V_i} \|x - p_i\| \varphi(x) dx$$

Lower bound (most useful when $\lambda \to 0^{+1}$

For all policies π : $\overline{T}_{\pi} \geq \mathbb{E}_{\omega}[\min_{i} ||X - p_{i}^{*}||]/v + \overline{s}$

Proof sketch:

 multi-median: best a priori location to reach a newly arrived demand

Dynamic Vehicle Routing (Lecture 4/8)

Dynamic Vehicle Routing (Lecture 4/8) 29jun10 @ Baltimore, ACC

Heavy-load lower bound

Heavy-load lower bound

spatially-unbiased policies: $\overline{T}_{\pi} \geq \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda \, \left(\int_{\mathcal{Q}} \varphi^{1/2}(x) dx \right)^2}{m^2 \, v^2 \, (1-\varrho)^2}$ as $\varrho \to 1^-$

spatially-biased policies: $\overline{T}_{\pi} \geq \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda \, \left(\int_{\mathcal{Q}} \varphi^{2/3}(x) dx \right)^3}{m^2 \, v^2 \, (1-\alpha)^2}$ as $\varrho \to 1^-$

- Recall inter-demand distance $\overline{D} \geq \beta_{\mathrm{TSP}} \, \frac{\int_{\mathcal{Q}} \varphi^{1/2}(x) dx}{\sqrt{2 \, \overline{M}}}$, as $\varrho \to 1^-$
- for stability with *m* vehicles:

$$\bar{s} + \frac{\overline{D}}{v} \le \frac{m}{\lambda} \implies \bar{s} + \beta_{\mathrm{TSP}} \frac{\int_{\mathcal{Q}} \varphi^{1/2}(x) dx}{v \sqrt{2 \, \overline{N}}} \le m/\lambda$$

• $\overline{N} = \lambda \overline{W}$ and $\overline{T} = \overline{W} + \overline{s}$ \Longrightarrow $\overline{T}^* \geq \frac{\beta_{\text{TSP}}^2}{2} \frac{\lambda \left(\int_{\mathcal{Q}} \varphi^{1/2}(x) dx \right)}{2}$

Heavy-load lower bound

Heavy-load lower bound

spatially-unbiased policies: $\overline{T}_{\pi} \geq \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda \, \left(\int_{\mathcal{Q}} \varphi^{1/2}(x) dx \right)^2}{m^2 \, v^2 \, (1-\varrho)^2}$ as $\varrho \to 1^-$

spatially-biased policies: $\overline{T}_{\pi} \geq \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda \, \left(\int_{\mathcal{Q}} \varphi^{2/3}(x) dx\right)^3}{m^2 \, v^2 \, (1-\alpha)^2}$ as $\varrho \to 1^-$

Proof sketch (for unbiased policies):

- Recall inter-demand distance $\overline{D} \geq \beta_{\mathrm{TSP}} \frac{\int_{\mathcal{Q}} \varphi^{1/2}(x) dx}{\sqrt{2 \, \overline{N}}}$, as $\varrho \to 1^-$
- for stability with m vehicles:

$$\bar{s} + \frac{\overline{D}}{v} \le \frac{m}{\lambda} \implies \bar{s} + \beta_{\mathrm{TSP}} \frac{\int_{\mathcal{Q}} \varphi^{1/2}(x) dx}{v \sqrt{2} \, \overline{N}} \le m/\lambda$$

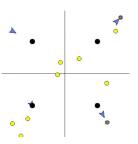

• $\overline{N} = \lambda \overline{W}$ and $\overline{T} = \overline{W} + \overline{s}$ \Longrightarrow $\overline{T}^* \ge \frac{\beta_{\mathrm{TSP}}^2}{2} \frac{\lambda \left(\int_{\mathcal{Q}} \varphi^{1/2}(x) dx \right)^2}{m^2 v^2 (1-a)^2}$

An optimal light-load policy

m Stochastic Queueing Median (mSQM)

Compute multi-median p^* and assign one vehicle at each median point. Then:

- 1: Assign demand that falls in V_i to vehicle i
- 2: each vehicles service demands in FCFS order
- 3: each vehicle returns to p_k^* after each service is completed

- As $\lambda \to 0^+$, \mathbb{P} [demand generated when system is empty] $\to 1$
- \Rightarrow all demands are generated with the vehicles at p^*

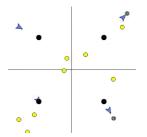

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 4/8) 29jun10 @ Baltimore, ACC

An optimal light-load policy

m Stochastic Queueing Median (mSQM)

Compute multi-median p^* and assign one vehicle at each median point. Then:

- 1: Assign demand that falls in V_i to vehicle i
- 2: each vehicles service demands in FCFS order
- 3: each vehicle returns to p_k^* after each service is completed

Proof sketch of optimality

- As $\lambda \to 0^+$, \mathbb{P} [demand generated when system is empty] $\to 1$
- \Rightarrow all demands are generated with the vehicles at p^*

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 4/8) 29jun10 @ Baltimore, ACC

An optimal spatially-unbiased heavy-load policy

Unbiased TSP (UTSP)

Partition Q into r subregions Q_k with $\int_{Q_k} \varphi(x) dx = 1/r$. Then:

- 1: within each subregion form sets of size n/r
- 2: deposit sets in a queue
- 3: service sets FCFS with the first available vehicle by following a TSP tour

Optimize over *n*.

Optimality of UTSP policy

$$\lim_{\varrho \to 1^-} \overline{T}_{\rm UTSP}(r)/\overline{T}_{\rm U}^* \ \le \ 1 + 1/r$$

reduction to GI/G/m

An optimal spatially-unbiased heavy-load policy

Unbiased TSP (UTSP)

Partition Q into r subregions Q_k with $\int_{Q_k} \varphi(x) dx = 1/r$. Then:

- 1: within each subregion form sets of size n/r
- 2: deposit sets in a queue
- 3: service sets FCFS with the first available vehicle by following a TSP tour

Optimize over *n*.

Optimality of UTSP policy

$$\lim_{\varrho \to 1^-} \overline{T}_{\mathsf{UTSP}}(r)/\overline{T}_{\mathsf{U}}^* \ \le \ 1 + 1/r$$

Proof sketch of optimality (r=1)

reduction to GI/G/m

Lecture outline

M. Pavone, E. Frazzoli, and F. Bullo. Distributed and adaptive algorithms for vehicle routing in a stochastic and dynamic environment. IEEE Transactions on Automatic Control, May 2010. (Submitted, Apr 2009) to appear

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 4/8) 29jun10 @ Baltimore, ACC

FB, EF, MP, KS, SLS (UCSB, MIT)

Motivation

Performance:

heavy load:

Implementation:

multi-vehicle policies

multi-vehicle policies

Dynamic Vehicle Routing (Lecture 4/8) 29jun10 @ Baltimore, ACC

• light load: problem reduces to locational optimization

1 delay of optimal single vehicle policy scales as $\lambda |Q|$

② by (equitably) partitioning, delay reduces to $\frac{\lambda}{m} \frac{|\dot{Q}|}{m} = \frac{\lambda |\dot{Q}|}{m^2}$ ③ \Rightarrow delay scales as m^{-2} , as in the lower bound

• systematic approach to lift adaptive single-vehicle policies to

Motivation

Performance:

- light load: problem reduces to locational optimization
- heavy load:
 - **1** delay of optimal single vehicle policy scales as $\lambda |Q|$
 - ② by (equitably) partitioning, delay reduces to $\frac{\lambda}{m} \frac{|\mathcal{Q}|}{m} = \frac{\lambda |\mathcal{Q}|}{m^2}$ ③ \Rightarrow delay scales as m^{-2} , as in the lower bound

- systematic approach to lift adaptive single-vehicle policies to
- coupled with distributed partitioning algorithms, provides distributed

Partitioning policies

subregion

Definition $(\pi$ -partitioning policy)

Given m vehicles and single-vehicle policy π : • Workspace divided into *m* subregions

One-to-one correspondence vehicles/subregions

3 Each agent executes the single-vehicle policy π within its own

Dynamic Vehicle Routing (Lecture 4/8)

• coupled with distributed partitioning algorithms, provides distributed

FB, EF, MP, KS, SLS (UCSB, MIT)

Motivation

Performance:

- light load: problem reduces to locational optimization
- heavy load:
 - **1** delay of optimal single vehicle policy scales as $\lambda |Q|$
 - ② by (equitably) partitioning, delay reduces to $\frac{\lambda}{m} \frac{|\mathcal{Q}|}{m} = \frac{\lambda |\mathcal{Q}|}{m^2}$ ③ \Rightarrow delay scales as m^{-2} , as in the lower bound

Implementation:

- systematic approach to lift adaptive single-vehicle policies to multi-vehicle policies
- coupled with distributed partitioning algorithms, provides distributed multi-vehicle policies

distributed multi-vehicle policy = single-vehicle policy + optimal partitioning + distributed algorithm for partitioning

Dynamic Vehicle Routing (Lecture 4/8)

29jun10 @ Baltimore, ACC

Optimal partitioning in heavy load

Intuition

- per-vehicle workload is $\propto \lambda \int_{\mathcal{O}_{k}} \varphi(x) dx$
- per-vehicle service capacity is $\propto \lambda \int_{\mathcal{O}_L} \varphi^{1/2}(x) dx$
- optimal partitioning = equalizing per-vehicle workload and service capacity

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 4/8) 29jun10 @ Baltimore, ACC

Optimal partitioning in heavy load

Intuition

- per-vehicle workload is $\propto \lambda \int_{\mathcal{O}_L} \varphi(x) dx$
- per-vehicle service capacity is $\propto \lambda \int_{\mathcal{Q}_k} \varphi^{1/2}(x) dx$
- optimal partitioning = equalizing per-vehicle workload and service capacity

Definition

A partition $\{Q_k\}_{k=1}^m$ is:

- equitable if $\int_{\mathcal{O}_{\nu}} \varphi(x) dx = \int_{\mathcal{O}} \varphi(x) dx / m$
- simultaneously equitable if

 - 2 $\int_{\Omega_{1}} \varphi^{1/2}(x) dx = \int_{\Omega} \varphi^{1/2}(x) dx / m$

Optimal partitioning in heavy load

Intuition

- per-vehicle workload is $\propto \lambda \int_{\mathcal{O}_L} \varphi(x) dx$
- per-vehicle service capacity is $\propto \lambda \int_{\mathcal{Q}_{k}} \varphi^{1/2}(x) dx$
- optimal partitioning = equalizing per-vehicle workload and service capacity

Definition

A partition $\{Q_k\}_{k=1}^m$ is:

- equitable if $\int_{\mathcal{O}_{+}} \varphi(x) dx = \int_{\mathcal{O}} \varphi(x) dx/m$
- simultaneously equitable if

 - 2 $\int_{\mathcal{O}_k} \varphi^{1/2}(x) dx = \int_{\mathcal{O}} \varphi^{1/2}(x) dx / m$

Simultaneously equitable partitions exist for any Q and φ

(S. Bespamyatnikh, D. Kirkpatrick, and J. Snoeyink, 2000)

Optimal partitioning in heavy load

Theorem

Given single-vehicle optimal policy π^* , a π^* -partitioning policy using a simultaneously equitable partition is an optimal unbiased policy

Proof sketch

- $\mathbb{P}\left[\text{demand arrives in } \mathcal{Q}_k\right] = \int_{\mathcal{Q}_k} \varphi(x) \, dx = 1/m$
- arrival rate in region k: $\lambda_k = \lambda/m$
- $\Rightarrow \varrho_k = \lambda_k \bar{s} = \lambda \bar{s}/m = \varrho < 1 \Rightarrow$ system is stable
- conditional density for region k: $\varphi(x)/\Big(\int_{\mathcal{Q}_k}\varphi(x)\,dx\Big)=m\,\varphi(x)$
- $\overline{T} = \sum_{k=1}^{m} \left(\int_{\mathcal{Q}_k} \varphi(x) \, dx \, \frac{\beta_{\mathrm{TSP}}^2}{2} \, \frac{\lambda_k}{v^2 \, (1-\varrho_k)^2} \, \left[\int_{\mathcal{Q}_k} \sqrt{\frac{\varphi(x)}{\int_{\mathcal{Q}_k} \varphi(x) \, dx}} \, dx \right]^2 \right)$ $=\sum_{k=1}^{m} \frac{1}{m} \overline{T}_{\pi^*} \frac{1}{m^2}$

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 4/8) 29jun10 @ Baltimore, ACC

FB, EF, MP, KS, SLS (UCSB, MIT)

Special cases

stability not an issue:

Case $\bar{s} = 0$:

Dynamic Vehicle Routing (Lecture 4/8)

 $- m \cdot \frac{n}{\mathsf{TSPlength}(n)} = \mathsf{demand} \; \mathsf{growth} \; \mathsf{rate}$

per-vehicle service capacity is unbalanced ⇒ policy stable but not

 \bullet guaranteed to be within m of optimal unbiased performance

Comments

If $\{Q_k\}_{k=1}^m$ is only equitable wrt to $\varphi^{1/2}$...

- $\exists \bar{k}$ such that $\rho_{\bar{k}} = \lambda (1/m + \varepsilon) \bar{s} = \rho + \varepsilon \lambda \bar{s}$
- potentially, policy unstable for $\rho < 1!$

If $\{Q_k\}_{k=1}^m$ is only equitable wrt to φ ...

- per-vehicle service capacity is unbalanced ⇒ policy stable but not optimal
- guaranteed to be within m of optimal unbiased performance

Comments

If $\{Q_k\}_{k=1}^m$ is only equitable wrt to $\varphi^{1/2}$...

• potentially, policy unstable for $\rho < 1!$

• $\exists \bar{k}$ such that $\rho_{\bar{k}} = \lambda (1/m + \varepsilon) \bar{s} = \rho + \varepsilon \lambda \bar{s}$

Dynamic Vehicle Routing (Lecture 4/8)

ullet equitability only wrt to $\varphi^{1/2}$ provides optimal performance

• since TSPlength(n) $\propto \sqrt{n} \Rightarrow$ stability for all λ, m

• no need to use algorithms for simultaneous equitability

• equitable wrt to $\varphi \Rightarrow$ equitable wrt to $\varphi^{1/2}$

Special cases

Case $\bar{s} = 0$:

• stability not an issue:

$$\underbrace{\lambda}_{\text{generation rate}} - \underbrace{m \cdot \frac{n}{\mathsf{TSPlength}(n)}}_{\text{service rate}} = \mathsf{demand growth rate}$$

- since TSPlength(n) $\propto \sqrt{n} \Rightarrow$ stability for all λ, m
- ullet equitability only wrt to $\varphi^{1/2}$ provides optimal performance

Case $\varphi = \text{uniform}$:

- \bullet equitable wrt to $\varphi \Rightarrow$ equitable wrt to $\varphi^{1/2}$
- no need to use algorithms for simultaneous equitability

Equitable and median Voronoi diagrams with synchronous

"Ambitious" goal:

Distributed algorithm to partition the workspace according to:

- median Voronoi diagram (relevant in light-load)
- equitable (relevant in heavy load)

proximity-graphs communication

Equitable and median Voronoi diagrams with synchronous proximity-graphs communication

"Ambitious" goal:

Distributed algorithm to partition the workspace according to:

- median Voronoi diagram (relevant in light-load)
- equitable (relevant in heavy load)

Voronoi Diagrams

Voronoi partition $\{V_1, \ldots, V_m\}$ generated by points (p_1, \ldots, p_m) :

$$V_i = \{x \in \mathcal{Q} \mid ||x - p_i||^2 \leqslant ||x - p_j||^2, \forall j \neq i\}$$

Dynamic Vehicle Routing (Lecture 5/8)

29jun10 @ Baltimore, ACC

Equitable and median Voronoi diagrams with synchronous proximity-graphs communication

"Ambitious" goal:

Distributed algorithm to partition the workspace according to:

- median Voronoi diagram (relevant in light-load)
- equitable (relevant in heavy load)

Voronoi Diagrams

Voronoi partition $\{V_1, \ldots, V_m\}$ generated by points (p_1, \ldots, p_m) :

$$V_i = \{x \in \mathcal{Q} \mid ||x - p_i||^2 \leqslant ||x - p_j||^2, \forall j \neq i\}$$

In general, an equitable Voronoi Diagram fails to exist...

Dynamic Vehicle Routing (Lecture 5/8)

Partitioning using Power Diagrams

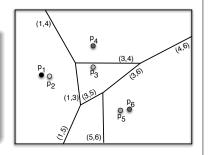

Power distance

- $p = (p_1, \dots, p_m)$ collection of points in $\mathcal{Q} \subset \mathbb{R}^2$
- each p_i has assigned a weight $w_i \in \mathbb{R}$
- power distance function $d_P(x, p_i; w_i) = ||x p_i||^2 w_i$

Power Diagrams

Power diagram $\{V_1, \ldots, V_m\}$ generated by weighted points $((p_1, w_1), \ldots, (p_m, w_m))$:

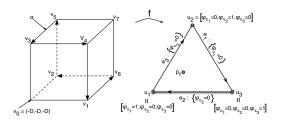

•
$$V_i = \{x \in \mathcal{Q} | ||x - p_i||^2 - w_i \le ||x - p_i||^2 - w_i, \forall j \ne i\}$$

Existence theorem for Power diagrams

Existence theorem

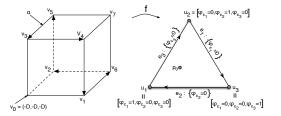

Let $p = (p_1, \dots, p_m)$ be the positions of $m \ge 1$ distinct points in Q. Then there exist weights (w_1, \ldots, w_m) such that the corresponding Power diagram is equitable with respect to φ

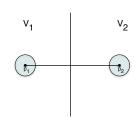

Existence theorem for Power diagrams

Existence theorem

Let $p = (p_1, \ldots, p_m)$ be the positions of $m \ge 1$ distinct points in Q. Then there exist weights (w_1, \ldots, w_m) such that the corresponding Power diagram is equitable with respect to φ

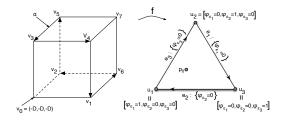

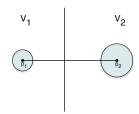

Existence theorem for Power diagrams

Existence theorem

Existence theorem for Power diagrams

Existence theorem

Let $p = (p_1, \dots, p_m)$ be the positions of $m \ge 1$ distinct points in Q. Then there exist weights (w_1, \ldots, w_m) such that the corresponding Power diagram is equitable with respect to φ

Gradient descent law for equitable partitioning

- w_i locally controlled by vehicle i
- locational optimization function

$$\mathcal{H}(w) \doteq \sum_{i=1}^{m} \left(\int_{V_i(w)} \varphi(x) dx \right)^{-1} = \sum_{i=1}^{m} |V_i(w)|_{\varphi}^{-1}$$

• spatially-distributed gradient: $\frac{\partial \mathcal{H}}{\partial w_i} = \sum_{j \in N_i} \alpha_{ij}^{\varphi} \left(\frac{1}{|V_j|_{\varphi}^2} - \frac{1}{|V_i|_{\varphi}^2} \right)$

Gradient law for equitable partitioning

At each comm round:

- 1: acquire neighbors' positions
- 2: compute own dominance region
- 3: $w_i \leftarrow w_i \gamma \frac{\partial \mathcal{H}}{\partial w_i}$

Dynamic Vehicle Routing (Lecture 5/8)

29jun10 @ Baltimore, ACC

22 / 1/

Including the median Voronoi diagram property

Close to Voronoi:

- basic idea: keep the weights *close* to zero
- modify the gradient descent law as

$$\dot{w}_i = -\frac{\partial \mathcal{H}}{\partial w_i} - w_i, \qquad \frac{\partial \mathcal{H}}{\partial p_i} \cdot \dot{p}_i - \frac{\partial \mathcal{H}}{\partial w_i} w_i = 0$$

Motion toward the median:

- basic idea: add a term that enforces computation of the median
- gradient term for computation of the median:

$$\frac{\partial \mathcal{H}_{FW}}{\partial p_i} = \int_{V_i} \frac{p_i - x}{\|p_i - x\|} \varphi(x) dx$$

modify the gradient descent law as

$$\dot{w}_i = -\frac{\partial \mathcal{H}}{\partial w_i}, \qquad \dot{p}_i = \frac{\partial \mathcal{H}_{\mathsf{FW}}}{\partial p_i} \ \psi\Big(\frac{\partial \mathcal{H}}{\partial p_i}, \frac{\partial \mathcal{H}_{\mathsf{FW}}}{\partial p_i}\Big)$$

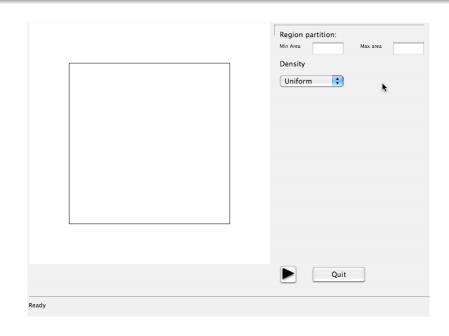

Convergence result

Theorem (Convergence)

Assume that the p_i 's are distinct. Then, the w_i 's converge asymptotically to a vector of weights that yields an equitable Power diagram

- guaranteed convergence for any set of distinct points
 ⇒ global convergence result
- distributed over the dual graph of the induced Power diagram
 communication, on average, with six neighbors
- adjusting the weights sufficient to obtain an equitable diagram
 ⇒ move the p_i's to optimize secondary objectives

Simulation

Lecture outline

- Partitioning with gossip (asynchronous pair-wise) communication
- - No explicit communication policy
 - Game-theoretic interpretation

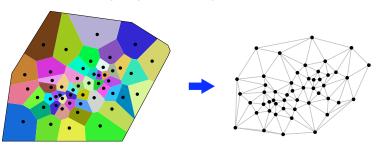

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 5/8)

Partitioning with gossip communication

Voronoi+centering law requires:

- synchronous communication
- 2 communication along edges of dual graph

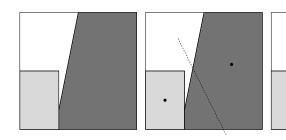

Minimalist coordination

- is synchrony necessary?
- is it sufficient to communicate peer-to-peer (gossip)?
- what are minimal requirements?

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 5/8) 29jun10 @ Baltimore, ACC

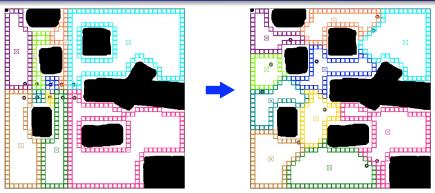

Gossip (asynchronous pair-wise) partitioning policy

- Random communication between two regions
- 2 Compute two centers
- Ompute bisector of centers
- Partition two regions by bisector

Peer-to-peer convergence analysis (proof sketch 1/3)

Lyapunov function for peer-to-peer territory partitioning

$$\mathcal{H}(v) = \sum_{i=1}^n \int_{v_i} f(\|\operatorname{center}(v_i) - q\|) \phi(q) dq$$

Dynamic Vehicle Routing (Lecture 5/8)

Dynamic Vehicle Routing (Lecture 5/8)

The space of partitions (proof sketch 2/3)

Definition (Space of finitely-convex partitions)

Fix ℓ , the set ν is collections of n subsets of Q, $\{v_1, \ldots, v_n\}$, such that

- $v_1 \cup \cdots \cup v_n = Q$
- ② interior $(v_i) \cap interior(v_i) = \emptyset$ if $i \neq i$, and
- **3** each v_i is union of ℓ convex sets

Given sets A and B, symmetric distance is:

$$d_{\Delta}(A,B) = \operatorname{area}\left((A \cup B) \setminus (A \cap B)\right)$$

Theorem (topological properties of the space of finitely-convex partitions)

Partition space with $(u, v) \mapsto \sum_{i=1}^{n} d_{\Delta}(u_i, v_i)$ is metric and compact

Peer-to-peer convergence analysis (proof sketch 1/3)

Lyapunov function for peer-to-peer territory partitioning

$$\mathcal{H}(v) = \sum_{i=1}^n \int_{v_i} f(\|\operatorname{center}(v_i) - q\|) \phi(q) dq$$

- 1 state space is not finite-dimensional non-convex disconnected polygons arbitrary number of vertices
- 2 peer-to-peer map is not deterministic, ill-defined and discontinuous two regions could have same centers

FB, EF, MP, KS, SLS (UCSB, MIT)

Convergence with persistent switches (proof sketch 3/3)

- X is metric space
- finite collection of maps $T_i: X \to X$ for $i \in I$
- consider sequences $\{x_\ell\}_{\ell>0} \subset X$ with

$$x_{\ell+1} = T_{i(\ell)}(x_{\ell})$$

Assume:

- ullet $W \subset X$ compact and positively invariant for each T_i
- ② $U: W \to \mathbb{R}$ decreasing along each T_i
- \odot U and T_i are continuous on W
- there exists probability $p \in [0,1]$ such that, for all indices $i \in I$ and times ℓ , we have $Prob \left[x_{\ell+1} = T_i(x_{\ell}) \mid past \right] \geq p$

If $x_0 \in W$, then almost surely

 $x_{\ell} \rightarrow \text{ (intersection of sets of fixed points of all } T_i) \cap U^{-1}(c)$

Dynamic Vehicle Routing (Lecture 5/8) 29jun10 @ Baltimore, ACC

Dynamic Vehicle Routing (Lecture 5/8)

Motivation

Gradient policy

- Cost function: $\mathcal{H}(p) = \sum_{j=1}^n \int_{V_j(p)} \|q p_j\| \varphi(q) dq$
- $\dot{p}_i = -\frac{\partial \mathcal{H}}{\partial p_i}(p) = -\int_{V_i(p)} \frac{\partial}{\partial p_i} \|q p_i\|\varphi(q)dq$
- p(t) converges to a critical point of $\mathcal{H}(p)$
- Similar result using the gossip partitioning policy

Salient Features

- Explicit agent-to-agent communication
- Needs knowledge of φ

Motivation

Gradient policy

- Cost function: $\mathcal{H}(p) = \sum_{j=1}^n \int_{V_i(p)} \|q p_j\| \varphi(q) dq$
- $\dot{p}_i = -\frac{\partial \mathcal{H}}{\partial p_i}(p) = -\int_{V_i(p)} \frac{\partial}{\partial p_i} ||q p_i||\varphi(q)dq$
- p(t) converges to a critical point of $\mathcal{H}(p)$
- Similar result using the gossip partitioning policy

Partitioning with no explicit inter-vehicle communication

Inspiration: Distributed MacQueen algorithm

- Pick any m generator points $(p_1, \ldots, p_m) \in \mathcal{Q}^m$
- Iteratively sample points q_i according to probability density function φ
- At each iteration j:
 - Assign the sampled point to the nearest generator $i^*(q_i) \in \{1, \dots, m\}$
 - update the position of generator i^* as

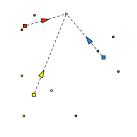

$$p_{i^*} = \frac{\left(\# \mathsf{pts} \; \mathsf{assigned} \; \mathsf{in} \; \mathsf{past}\right) p_{i^*} + q_j}{\# \mathsf{pts} \; \mathsf{assigned} \; \mathsf{in} \; \mathsf{past} + 1}$$

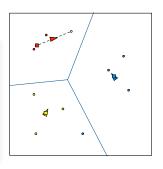

Algorithms

No sensor policy

For all time *t*, each vehicle moves towards:

- the nearest outstanding task; else,
- the (nearest) point minimizing the average distance to tasks serviced in the past

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 5/8)

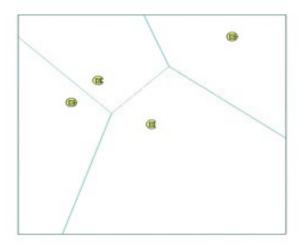

29jun10 @ Baltimore, ACC

Algorithms

No sensor policy

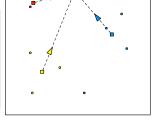

29jun10 @ Baltimore, ACC

Illustration

Dynamic Vehicle Routing (Lecture 5/8)

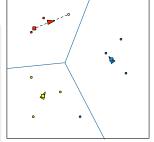

- For all time *t*, each vehicle moves towards: • the nearest outstanding task; else,
 - the (nearest) point minimizing the average distance to tasks serviced in the past

Sensor-based policy

For all time t, each vehicle moves towards:

- the nearest among outstanding tasks that is closest to it than other vehicles; else,
- the (nearest) point minimizing the average distance to tasks serviced in the past

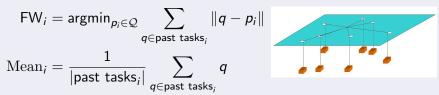

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 5/8)

Differences with the MacQueen algorithm

• At each iteration, the no-communication algorithm computes the "Fermat-Weber (FW) point" with respect to the set of tasks serviced by a vehicle; MacQueen algorithm computes the mean

$$\mathsf{FW}_i = \mathsf{argmin}_{p_i \in \mathcal{Q}} \sum_{q \in \mathsf{past} \; \mathsf{tasks}_i} \|q - p_i\|$$

- ullet No simple recursion like the MacQueen algorithm o need to store locations of all the tasks serviced in the past
- Sequence of FW points exhibit more complex behavior than the sequence of means.

Analysis of the algorithm

- $p_i(t)$: loitering location of agent i at time t
- Sufficient to study convergence of $(p_1(t), \ldots, p_m(t))$

FB, EF, MP, KS, SLS (UCSB, MIT)

29jun10 @ Baltimore, ACC

Analysis of the algorithm

- $p_i(t)$: loitering location of agent i at time t
- Sufficient to study convergence of $(p_1(t), \ldots, p_m(t))$

Convergence result

p(t) converges to a critical point of $\mathcal{H}(p)$ with probability one.

Key steps in the proof

- Convergence of the sequence of Fermat-Weber points:
 - $C_i(t) := \{ y \in \mathcal{Q} \mid \| \sum_{q \in \mathsf{past} \; \mathsf{tasks}_i} \mathsf{vers}(y q) \| \le 1 \}$
 - By the properties of the Fermat-Weber point, $p_i(t_i) \in C_i(t_i)$
 - Prove that $p_i(t_{i+1}) \in C_i(t_i)$
 - Prove that $\lim_{i\to\infty} \operatorname{diam}(C_i(t_i)) = 0$ with prob. 1; this implies $p_i(t_i) \rightarrow p_i^*$ with prob 1
- p_i^* is the median of its own Voronoi cell

Dynamic Vehicle Routing (Lecture 5/8)

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 5/8)

Lecture outline

- 5 Partitioning with no explicit inter-vehicle communication
 - No explicit communication policy
 - Game-theoretic interpretation

Coverage as a geometric game

Strategies

- \bullet $p = (p_1, \ldots, p_m) \in \mathcal{Q}^m$
- When a new task is generated, every vehicle move towards its location

$$\mathcal{U}_i(p_i, p_{-i}) = \mathbb{E}_{\varphi}[R_i(p, q)] = \mathbb{E}_{\varphi}\left[\max\left\{0, \min_{j \neq i}\|p_j - q\| - \|p_i - q\|\right\}\right]$$

Coverage as a geometric game

Strategies

- $p = (p_1, \ldots, p_m) \in \mathcal{Q}^m$
- When a new task is generated, every vehicle move towards its location

Utility Function

- Upon its generation, each task offers continuous reward at rate unity
- A task expires as soon as two vehicles are present at its location or after diam(Q) time, whichever occurs first.
- Utility function: expected time spent alone at the next task location

$$\mathcal{U}_i(p_i,p_{-i}) = \mathbb{E}_{arphi}[R_i(p,q)] = \mathbb{E}_{arphi}\left[\max\left\{0,\min_{j
eq i}\|p_j-q\|-\|p_i-q\|
ight\}
ight]$$

Dynamic Vehicle Routing (Lecture 5/8) 29jun10 @ Baltimore, ACC

Properties of the Game

• Potential function: $\psi(p) = -\sum_{i=1}^m \int_{V_i(p)} \|p_i - q\|\varphi(q)dq$

• The coverage spatial game is a potential game $(\mathcal{U}_i(p) = \psi(p) - \psi(p_{-i}))$

 \bullet \mathcal{U} is a Wonderful Life utility function

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 5/8)

Properties of the Game

DVR with stochastic time constraints

Model:

- basic DVR model +
- demand *j* active for a random patience time G_i
- G_i 's i.i.d. sequence $\sim F_G$
- demand j expires if not serviced within G_i

Service constraint:

- $\lim_{i \to +\infty} \mathbb{P}_{\pi}[W_i < G_i]$: acceptance probability for policy π
- $\phi^{\rm d} \in (0, 1)$: desired acceptance probability

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 6/8)

29jun10 @ Baltimore, ACC

Lower bound

Intuition for lower bound:

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 6/8)

 $\leq \sup_{(p_1,\ldots,p_m)\in\mathcal{Q}^m} \mathbb{P}\left[\min_{k\in\{1,\ldots,m\}}\frac{\|X_j-p_k\|}{v} < G_j\right]$

• regeneration points: times a new demand finds the system empty

main idea: theory of regenerative processes

expected length of busy cycles is finite

 $\min_{\pi} \quad |\pi|, \quad ext{subject to} \quad \lim_{i \to \infty} \mathbb{P}_{\pi} \left[W_j < \mathit{G}_j
ight] \geq \phi^{\mathrm{d}}$

29jun10 @ Baltimore, ACC

Problem formulation

Problem statement

Solve problem *OPT*:

$$\min_{\pi} \quad |\pi|, \quad ext{subject to} \quad \lim_{j \to \infty} \mathbb{P}_{\pi} \left[W_j < \mathit{G}_j
ight] \geq \phi^{\mathrm{d}}$$

Well-posedness

- Existence: $\lim_{i\to\infty} \mathbb{P}_{\pi}[W_i < G_i]$ exists for all π
- Ergodicity: $\lim_{i\to\infty} \mathbb{P}_{\pi} [W_i < G_i] = \lim_{t\to+\infty} N^s(t)/N(t)$ (a.s.)

Proof sketch:

- main idea: theory of regenerative processes
- regeneration points: times a new demand finds the system empty
- expected length of busy cycles is finite
- use classic limit theorems

- constraint: $\lim_{i \to +\infty} \mathbb{P}_{\pi} [W_i < G_i] \ge \phi^{\mathrm{d}}$

Problem formulation

Problem statement

Solve problem *OPT*:

 $\mathbb{P}\left[W_j < G_j\right] \leq \mathbb{P}\left[\min_{k \in \{1, \dots, m\}} \frac{\|X_j - X_k\|}{v} < G_j\right]$

Lower bound

Intuition for lower bound:

$$\mathbb{P}\left[W_{j} < G_{j}\right] \leq \mathbb{P}\left[\min_{k \in \{1, \dots, m\}} \frac{\|X_{j} - X_{k}\|}{v} < G_{j}\right]$$

$$\leq \sup_{(p_{1}, \dots, p_{m}) \in \mathcal{Q}^{m}} \mathbb{P}\left[\min_{k \in \{1, \dots, m\}} \frac{\|X_{j} - p_{k}\|}{v} < G_{j}\right]$$

$$\stackrel{\dot{=}\mathcal{H}(p_{1}, \dots, p_{m})}{=} \mathcal{H}(p_{1}, \dots, p_{m})$$

Lower bound

OPT is lower bounded by:

$$egin{aligned} rac{\mathit{OPT}}{m} : \min_{m \in \mathbb{N}_{>0}} & m \ & ext{s.t.} & \sup_{(p_1, \dots, p_m) \in \mathcal{Q}^m} \mathcal{H}(p_1, \dots, p_m) \geq \phi^{\mathrm{d}} \end{aligned}$$

Dynamic Vehicle Routing (Lecture 6/8)

29jun10 @ Baltimore, ACC

Lower bound

Proof sketch: • as usual, as $\lambda \to 0^+$, the problem reduces to optimal pre-positioning

Intuition for lower bound:

$$\mathbb{P}\left[W_{j} < G_{j}\right] \leq \mathbb{P}\left[\min_{k \in \{1, \dots, m\}} \frac{\|X_{j} - X_{k}\|}{v} < G_{j}\right]$$

$$\leq \sup_{(p_{1}, \dots, p_{m}) \in \mathcal{Q}^{m}} \underbrace{\mathbb{P}\left[\min_{k \in \{1, \dots, m\}} \frac{\|X_{j} - p_{k}\|}{v} < G_{j}\right]}_{\doteq \mathcal{H}(p_{1}, \dots, p_{m})}$$

Lower bound

OPT is lower bounded by:

$$\begin{array}{ccc} \underline{OPT} : \min_{m \in \mathbb{N}_{>0}} & m \\ & \text{s.t.} & \sup_{(p_1, \dots, p_m) \in \mathcal{Q}^m} \mathcal{H}(p_1, \dots, p_m) \geq \phi^{\mathrm{d}} \end{array}$$

Devised algorithms to solve OPT

Batch policy

Batch (B) policy

Partition Q into m simultaneously equitable subregions and assign one vehicle to each subregion. Then:

1: each vehicle services demands by forming TSP tours

Performance of batch policy

- if s=0: $m_{\mathsf{B}} = \min \left\{ m \middle| \sup_{\theta \in \mathbb{R}_{>0}} (1 F_{\mathsf{G}}(\theta)) (1 \frac{\lambda \cdot \mathrm{const}}{\theta m^2}) \ge \phi^{\mathrm{d}} \right\}$
- with time windows: $m_{\rm B}/m^* \leq 3.78$, when λ large and $\phi^d \to 1^-$

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 6/8)

29jun10 @ Baltimore, ACC

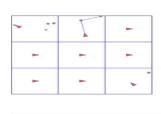

0 / 22

Characterization of batch policy

Proof sketch (m=1):

- upper bound expected length of TSP tour with $const \cdot \lambda/m^2$, via control-theoretical methods
- use Markov's ineq to lower bound:

$$\mathbb{P}\left[W < G\right] \ge \mathbb{P}\left[W < G|2\,\mathrm{TSP} < \theta\right] \mathbb{P}\left[2\,\mathrm{TSP} < \theta\right] \\ \ge (1 - F_G(\theta))(1 - \mathbb{E}[2\,\mathrm{TSP}]/\theta)$$

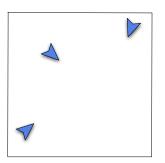

Lecture outline

Load Factor and Stability

Stable: Queue remains bounded

Define load factor as

$$\varrho := \frac{\lambda_1 \overline{s}_1 + \dots + \lambda_n \overline{s}_n}{m}$$

- λ_i = arrival rate for class i
- \bar{s}_i = average on-site service time for class i

As before, necessary stability condition is $\rho < 1$

Two asymptotic regimes

- Light load $\rho \rightarrow 0^+$
- 2 Heavy load $\rho \rightarrow 1^-$

Dynamic Vehicle Routing (Lecture 6/8) 29jun10 @ Baltimore, ACC

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 6/8) 29jun10 @ Baltimore, ACC

Light load

In light load:

- Each vehicle can return to a median between arrivals
- Priority levels do not change behavior.

Optimal solution:

m vehicle SQM policy is optimal (or an adaptive policy)

m Stochastic Queueing Median (m-SQM)

Compute *m*-median locations and assign one vehicle to each location.

Then:

- 1: service demands in FCFS order
- 2: return to median after each service is completed

Lower Bound in Heavy Load

Let $\overline{T}_c^* = \text{optimal value of cost } c_1 \overline{T}_1 + \cdots + c_n \overline{T}_n$

Lower bound for every policy

$$\overline{\mathcal{T}}_c^* \geq rac{eta_{ ext{TSP}}|Q|}{2 extit{m}^2 v^2 (1-arrho)^2} \sum_{lpha=1}^n \left(c_lpha + 2 \sum_{j=lpha+1}^n c_j
ight) \lambda_lpha$$

Problem parameters:

- arrival rates $\lambda_1, \ldots, \lambda_n$
- environment area |Q|

• weights c_1, \ldots, c_n

- vehicle speed v
- number of vehicles m

Proof Idea of Lower Bound

- Allow remote service of some classes: $r_{\alpha} \in \{0,1\}$ for each class α
- travel distance is $r_{\alpha} \bar{d}_{\alpha}$

- For stability: $\sum_{i=1}^{n} \lambda_i \left(r_i \bar{d}_i / v + \bar{s}_i \right) < m$
- Can bound travel distance as

$$ar{d}_{lpha} \geq rac{eta_{ ext{TSP}}}{\sqrt{2}} \sqrt{rac{|Q|}{\sum_{i} r_{i} \overline{N}_{i}}}$$

- generates a linear program with $2^n 1$ constraints, one for each combination $\{r_1, \ldots, r_n\}$
- solution to LP is largest lower bound

Dynamic Vehicle Routing (Lecture 6/8) 29jun10 @ Baltimore, ACC

Separate Queues Policy

Input: Probability distribution $\mathbf{p} = [p_1, \dots, p_n]$.

Separate Queues Policy

Partition environment into m equal area regions and assign one vehicle to each region.

Then:

- 1: Select a class according to probability dist p
- 2: Service all demands of selected class following TSP
- 3: Repeat

Policy performance optimized over **p**.

Dynamic Vehicle Routing (Lecture 6/8) 29jun10 @ Baltimore, ACC

Separate Queues Performance

Heavy load performance

For the SQ policy,

$$\frac{\overline{T}_{c,\mathrm{SQ}}}{\overline{T}_c^*} \le 2n^2$$

as $\varrho \to 1^-$.

- n = number of classes.
- independent of ϱ , c, \bar{s} , λ

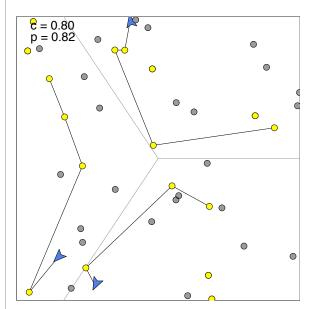

Heuristic Improvements:

- **1** Receding horizon: service only a fraction η of TSP
- 2 when following TSP, service newly arrived demands within ϵ of TSP.

$$\epsilon \sqrt{\frac{\mu|Q|}{\sum_{\alpha=1}^{n}\overline{N}_{\alpha}}},$$

where μ is fractional in tour length (i.e., 0.1 for 10% increase)

Simulation of Separate Queues Policy

Simulation:

- class 1 = yellow
- class 2 = grey
- $c_1 = 0.8$ and $c_2 = 0.2$
- $\mathbf{p} = [0.82, 0.18]$

Proof idea for upper bound

• In heavy-load, shortest path through N points:

$$=eta_{ ext{TSP}}\sqrt{|Q|N}$$
 with prob. 1 (BHH theorem)

• Study expected # of outstanding demands at each iteration

$$N_i(t+1) \leq f(N_1(t), \ldots, N_m(t), \mathbf{p}, \lambda, \bar{s})$$

- Function f has a linear part plus a sub-linear part
- ullet Bound evolution by stable linear system for all arrho < 1

$$\mathcal{N}(t+1) = A(\mathbf{p}, \lambda, \bar{s})\mathcal{N}(t) + B(\mathbf{p}, \lambda, \bar{s})$$

- ullet Allows computation of $\limsup_{t o +\infty} \mathcal{N}_i(t)$
- Apply Little's theorem $\overline{N}_i = \lambda_i \overline{T}_i$

Dynamic Vehicle Routing (Lecture 7/8)

Models of vehicles with differential constraints

2 Traveling salesperson problems

Outline of the lecture

- The heavy load case
- The light load case
- **6** Phase transition in the light load

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 7/8)

Vehicle routing with differential constraints

- What happens if the vehicles are subject to non-integrable differential constraints on their motion?
 - Minimum turn radius, constant speed (UAVs, Dubins cars)
 - Minimum turn radius, able to reverse (Reeds-Shepps cars)
 - Differential drive robots (e.g., tanks).
 - Bounded acceleration vehicles (e.g., helicopters, spacecraft).
- Fundamentally different problems, combining combinatorial task specifications with differential geometry and optimal control.
- Decompose the problem, study the asymptotic cases:
 - Heavy load: Traveling salesperson problems.
 - Light load: optimal loitering "stations".

Models of vehicles with differential constraints

Dubins vehicle

$$\dot{x} = \cos \theta$$
 $\dot{y} = \sin \theta$

$$\dot{\theta} = \omega$$

$$|\omega| \le 1/\rho$$

Reeds-Shepp car

$$\dot{x} = v \cos \theta
\dot{y} = v \sin \theta
\dot{\theta} = \omega$$

$$v \in \{-1, 1\}$$
$$|\omega| \le 1/\rho$$

Differential drive

$$\dot{x} = \frac{1}{2}(\omega_I + \omega_r)\cos\theta$$

$$\dot{y} = \frac{1}{2}(\omega_I + \omega_r)\sin\theta$$

$$\dot{\theta} = \frac{1}{2}(\omega_r - \omega_I)$$

Double integrator

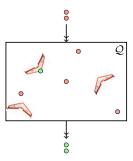

$$\ddot{x} = u$$
$$\|\dot{x}\| \le 1$$
$$\|u\| \le 1$$

DTRP formulation

Problem setup

- m identical vehicles in Q

Dynamic Vehicle Routing (Lecture 7/8)

29jun10 @ Baltimore, ACC

Dynamic Vehicle Routing (Lecture 7/8)

Traveling Salesperson Problem

Problem Statement

Find the shortest closed curve feasible for the vehicle through a given finite set of points in the plane

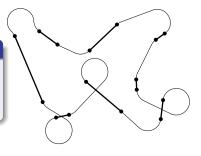

- NP-hardness a consequence of the NP-hardness of the Euclidean TSP.
- Does the cost of this TSP increase SUBLINEARLY with *n*?
- Is there a polynomial-time algorithm that returns a tour of length o(n)??
- What is the quality of the solution?

Traveling Salesperson Problem

Problem Statement

Find the shortest closed curve feasible for the vehicle through a given finite set of points in the plane

- NP-hardness a consequence of the NP-hardness of the Euclidean TSP.
- Is there a polynomial-time algorithm that returns a tour of length

Stochastic TSP: A nearest-neighbor lower bound

Outline of the calculations

- Calculate (an upper bound on) expected distance from an arbitrary vehicle configuration to closest point, δ^*
 - Calculate (an upper bound on) the area of the set reachable with a path of length δ , \mathcal{R}_{δ} .
 - $\Pr(\delta^* \geq \delta) \geq \max\{0, 1 n|\mathcal{R}_{\delta}|/|\mathcal{Q}|\}$
- Expected length of the tour cannot be less than n times $\mathbb{E}[\delta^*]$

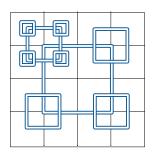

Dynamic Vehicle Routing (Lecture 7/8)

Dynamic Vehicle Routing (Lecture 7/8)

Towards an upper bound: tiling based algorithms

• The way the ETSP tours are constructed relies on the scaling properties of tours: the length of the tour scales as the coordinates of the points.

- No such scaling exists for the TSP for vehicles with differential
- Any tiling-based algorithm must account for a "preferential"

Stochastic TSP: A nearest-neighbor lower bound

Outline of the calculations

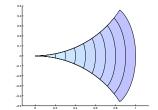

- Calculate (an upper bound on) expected distance from an arbitrary vehicle configuration to closest point, δ^*
 - Calculate (an upper bound on) the area of the set reachable with a path of length δ , \mathcal{R}_{δ} .
 - $\Pr(\delta^* > \delta) > \max\{0, 1 n|\mathcal{R}_{\delta}|/|\mathcal{Q}|\}$
- Expected length of the tour cannot be less than *n* times $\mathbb{E}[\delta^*]$

Example: Dubins vehicle

$$\bullet |\mathcal{R}_{\delta}| = rac{\delta^3}{3
ho}$$

•
$$\mathbb{E}[\delta^*] = \frac{3}{4} \left(\frac{3\rho|\mathcal{Q}|}{n} \right)^{1/3}$$

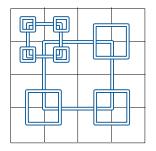

$$\begin{split} \bullet \ \mathbb{E}[\delta^*] &= \frac{3}{4} \left(\frac{3\rho|\mathcal{Q}|}{n}\right)^{1/3}. \\ \bullet \ \lim_{n \to \infty} \frac{\mathbb{E}[\mathrm{TSP}(n)]}{n^{2/3}} &\geq \frac{3}{4} (3\rho|\mathcal{Q}|)^{1/3}. \end{split}$$

FB, EF, MP, KS, SLS (UCSB, MIT)

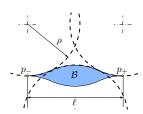

Towards an upper bound: tiling based algorithms

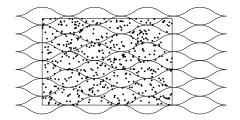

• The way the ETSP tours are constructed relies on the scaling properties of tours: the length of the tour scales as the coordinates of the points.

- No such scaling exists for the TSP for vehicles with differential constraints, e.g., the bound on the curvature for the Dubins vehicle does not scale with the coordinates of the points!
- Any tiling-based algorithm must account for a "preferential direction", e.g., by penalizing turning for Dubins vehicles

Bead construction

Bead properties

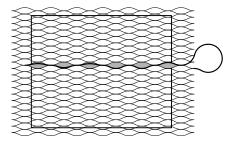

- Length $(p_-, q, p_+) \le \ell + o(\ell^2)$ for all $q \in \mathcal{B}$
- Width: $w(\ell) = \frac{\ell^2}{8\rho} + o(\ell^3)$
- The beads tile the plane
- Useful for Dubins vehicle, Reeds-Shepp car and double integrator

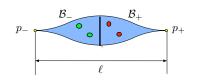

Dynamic Vehicle Routing (Lecture 7/8)

29jun10 @ Baltimore, ACC

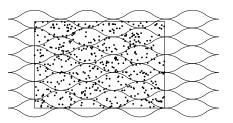

The single-sweep tiling algorithm

- Tile the region with beads
- Sweep the bead rows, while servicing all the targets in every bead as follows:
 - Service every task q in \mathcal{B}_{-} using the " $p_{-} \rightarrow q \rightarrow p_{-}$ " protocol
 - Move from p_{-} to p_{+}
 - ullet Service every task q in \mathcal{B}_+ using the " $p_+ o q o p_+$ " protocol

Bead construction

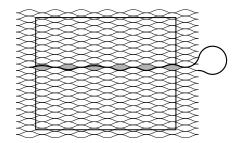

Bead properties

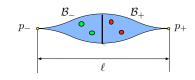

- Length $(p_-,q,p_+) \le \ell + o(\ell^2)$ for all $q \in \mathcal{B}$
- Width: $w(\ell) = \frac{\ell^2}{8\rho} + o(\ell^3)$
- The beads tile the plane
- Useful for Dubins vehicle, Reeds-Shepp car and double integrator
- Diamond-like cell for differential drive

Dynamic Vehicle Routing (Lecture 7/8)

The single-sweep tiling algorithm

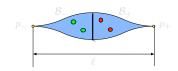

- Tile the region with beads
- Sweep the bead rows, while servicing all the targets in every bead as follows:
 - ullet Service every task q in \mathcal{B}_- using the " $p_- o q o p_-$ " protocol
 - Move from p₋ to p₊
 - Service every task q in \mathcal{B}_+ using the " $p_+ \to q \to p_+$ " protocol

Analysis of the single-sweep tiling algorithm

Path length calculations

 $TSP(n) = (bead row length + move to next bead row) \times \# bead rows + move to service each task <math>\times \# tasks + tour closure length$

• For a Reeds-Shepp car, as $\ell \to 0$:

$$TSP(n) \leq \left(\sqrt{|\mathcal{Q}|} + \ell/2\right) \frac{\sqrt{|\mathcal{Q}|}}{w(\ell)/2} + \ell n + 2\left(\sqrt{|\mathcal{Q}|} + \rho \pi\right)$$

$$\leq 16\rho \frac{|\mathcal{Q}|}{\ell^2} + 8\rho \frac{\sqrt{|\mathcal{Q}|}}{\ell} + \ell n + 2\left(\sqrt{|\mathcal{Q}|} + \rho \pi\right) \left(\because w(\ell) \approx \frac{\ell^2}{8\rho}\right)$$

• Pick $\ell = \left(\frac{32\rho|\mathcal{Q}|}{n}\right)^{1/3}$ (i.e., $\frac{|\mathcal{B}|}{|\mathcal{Q}|} = \frac{2}{n}$) \Longrightarrow TSP $(n) = O(n^{2/3})$.

Analysis of the single-sweep tiling algorithm

Path length calculations

 $TSP(n) = (bead row length + move to next bead row) \times \# bead rows + move to service each task <math>\times \# tasks + tour closure length$

• For a Dubins vehicle, as $\ell \to 0$:

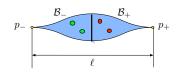

$$TSP(n) \leq \left(\sqrt{|\mathcal{Q}|} + \frac{w(\ell)}{2} + \kappa\right) \frac{\sqrt{|\mathcal{Q}|}}{w(\ell)/2} + (\ell + \kappa)n + 2\sqrt{|\mathcal{Q}|} + \kappa$$
$$\leq 16\rho \frac{|\mathcal{Q}|}{\ell^2} + \sqrt{|\mathcal{Q}|} + 16\kappa \frac{\sqrt{|\mathcal{Q}|}}{\ell^2} + \ell n + \kappa n + 2\sqrt{|\mathcal{Q}|} + \kappa$$

• The κn term grows linearly in n for all $\ell \implies \mathsf{TSP}(n) = O(n)$

Analysis of the single-sweep tiling algorithm

Path length calculations

 $TSP(n) = (bead row length + move to next bead row) \times \# bead rows +$ move to service each task × # tasks + tour closure length

• For a Dubins vehicle, as $\ell \to 0$:

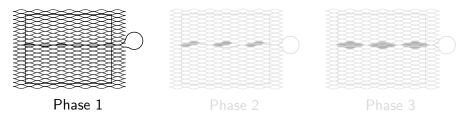

$$TSP(n) \leq \left(\sqrt{|\mathcal{Q}|} + \frac{w(\ell)}{2} + \kappa\right) \frac{\sqrt{|\mathcal{Q}|}}{w(\ell)/2} + (\ell + \kappa)n + 2\sqrt{|\mathcal{Q}|} + \kappa$$
$$\leq 16\rho \frac{|\mathcal{Q}|}{\ell^2} + \sqrt{|\mathcal{Q}|} + 16\kappa \frac{\sqrt{|\mathcal{Q}|}}{\ell^2} + \ell n + \kappa n + 2\sqrt{|\mathcal{Q}|} + \kappa$$

• The κn term grows linearly in n for all $\ell \implies \mathsf{TSP}(n) = O(n)$

Dynamic Vehicle Routing (Lecture 7/8)

The recursive sweep tiling algorithm

- Tile Q with beads such that: $\frac{|\mathcal{B}|}{|Q|} = \frac{1}{2n}$ (i.e., $\ell \sim n^{-1/3}$)
- Sweep the bead rows, visiting one target per non-empty bead.
- Iterate, using at the *i*-th phase a "meta-bead" composed of 2^{i-1} beads.
- After log n phases, visit the outstanding targets in any arbitrary order, e.g., with a greedy strategy.

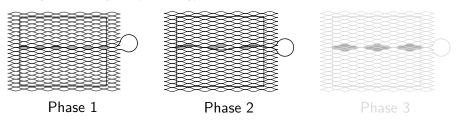

29jun10 @ Baltimore, ACC

Dynamic Vehicle Routing (Lecture 7/8)

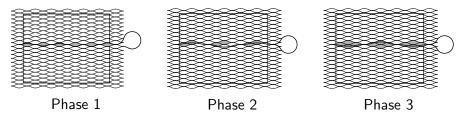

The recursive sweep tiling algorithm

- Tile ${\cal Q}$ with beads such that: $\frac{|{\cal B}|}{|{\cal Q}|}=\frac{1}{2n}\left(\text{i.e., }\ell\sim n^{-1/3}\right)$
- Sweep the bead rows, visiting one target per non-empty bead.
- Iterate, using at the *i*-th phase a "meta-bead" composed of 2^{i-1} beads.
- After log n phases, visit the outstanding targets in any arbitrary order, e.g., with a greedy strategy.

- Sweep the bead rows, visiting one target per non-empty bead.
- Iterate, using at the *i*-th phase a "meta-bead" composed of 2^{i-1} beads.
- After log n phases, visit the outstanding targets in any arbitrary order, e.g., with a greedy strategy.

Analysis of the recursive algorithm

• Theorem: For a Dubins vehicle, with probability one,

$$\limsup_{n\to\infty} \frac{\mathsf{TSP}(n)}{n^{2/3}} \leq 24\sqrt[3]{\rho|\mathcal{Q}|} \left(1 + \frac{7}{3}\pi \frac{\rho}{\sqrt{|\mathcal{Q}|}}\right)$$

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 7/8) 29jun10 @ Baltimore, ACC

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 7/8) 29jun10 @ Baltimore, ACC

Summary of TSPs

- Lower bound: $\mathbb{E}\left[\mathsf{TSP}(n)\right] \in \Omega(n^{2/3})$
- Upper bound: $\mathbb{E}\left[\mathsf{TSP}(n)\right] \in O(n^{2/3})$
- TSP(n) is of order $n^{2/3}$; constant factor approximation algorithms
- Computational complexity of the algorithms is of order n

$$\frac{\lambda}{\text{task generation rate}} - \underbrace{m \cdot \frac{n}{\text{TSP}(n)}}_{\text{task service rate}} = \text{task growth rate}$$

Analysis of the recursive algorithm

• Theorem: For a Dubins vehicle, with probability one,

$$\limsup_{n\to\infty} \frac{\mathsf{TSP}(n)}{n^{2/3}} \leq 24\sqrt[3]{\rho|\mathcal{Q}|} \left(1 + \frac{7}{3}\pi \frac{\rho}{\sqrt{|\mathcal{Q}|}}\right)$$

Outline of the proof

- $Pr(\lim_{n\to\infty} \# \text{ tasks remaining after phase } i^* > 24 \log n) = 0$
- Path length calculations:
 - Phase 1 path length $O\left(\frac{1}{\ell^2}\right) = O\left(n^{2/3}\right)$ (: $\ell \sim n^{-1/3}$)
 - Subsequent phase path lengths are decreasing geometric series; path length for all i^* phases is $O(n^{2/3})$
 - Path length by greedy heuristic is $O(\log n)$

Summary of TSPs

- Lower bound: $\mathbb{E}\left[\mathsf{TSP}(n)\right] \in \Omega(n^{2/3})$
- Upper bound: $\mathbb{E}\left[\mathsf{TSP}(n)\right] \in O(n^{2/3})$
- TSP(n) is of order $n^{2/3}$; constant factor approximation algorithms
- Computational complexity of the algorithms is of order n

Stabilizability of the DTRP

•
$$\lambda$$
task generation rate

 $m \cdot \frac{n}{\mathsf{TSP}(n)} = \mathsf{task} \; \mathsf{growth} \; \mathsf{rate}$
 $n: \# \; \mathsf{outstanding} \; \mathsf{tasks}$

• $\mathbb{E}[\mathsf{TSP}(n)] \in \Theta(n^{2/3}) \implies \mathsf{trivial} \mathsf{ receding horizon TSP-based}$ policies are stable for the DTRP for all λ and m

Outline of the lecture

- The heavy load case

Dynamic Vehicle Routing (Lecture 7/8)

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 7/8)

The heavy load case: nearest neighbor lower bound

Outline of the calculations

- Let n_{π} be the number of outstanding tasks at steady-state under stable policy π
- Calculate (an upper bound on) expected distance from an arbitrary vehicle configuration to closest among n_{π} points, $\delta^*(n_{\pi})$
- At steady-state: $\frac{\lambda}{m} = \frac{1}{\mathbb{E}[\delta^*(n_\pi)]}$
- Little's formula: $\lambda T_{\pi} = n_{\pi}$

Example: Dubins vehicle

- $\bullet \ \mathbb{E}[\delta^*(n_\pi)] = rac{3}{4} \left(rac{3
 ho|\mathcal{Q}|}{n_\pi}
 ight)^{1/3}$
- Steady state+ Little's formula: $\frac{\lambda}{m} = \frac{4}{3} \left(\frac{\lambda T_{\pi}}{3\rho |\mathcal{Q}|} \right)^{1/3}$
- $\liminf_{\frac{\lambda}{m}\to+\infty} \overline{T}^* \frac{m^3}{\lambda^2} \ge \frac{81}{64} \rho |\mathcal{Q}|$

The heavy load case: nearest neighbor lower bound

Outline of the calculations

- Let n_{π} be the number of outstanding tasks at steady-state under stable policy π
- Calculate (an upper bound on) expected distance from an arbitrary vehicle configuration to closest among n_{π} points, $\delta^*(n_{\pi})$
- At steady-state: $\frac{\lambda}{m} = \frac{1}{\mathbb{E}[\delta^*(n_{\pi})]}$
- Little's formula: $\lambda T_{\pi} = n_{\pi}$

The multiple sweep tiling algorithm

The single vehicle version

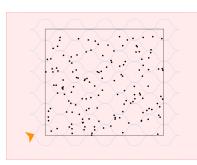

- \bullet Tile \mathcal{Q} with beads of length $\ell = c/\lambda$
- Update outstanding task list
- Execute single sweep tiling algorithm
- Goto 2.

The multiple sweep tiling algorithm

The single vehicle version

- \bullet Tile \mathcal{Q} with beads of length $\ell = c/\lambda$
- Update outstanding task list
- Secute single sweep tiling algorithm
- Goto 2.

The multi-vehicle version

- Divide Q into m equal "strips"
- Assign one vehicle to every strip
- Each vehicle executes the multiple sweep algorithm in its own strip

Dynamic Vehicle Routing (Lecture 7/8)

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 7/8)

Analysis of the multiple sweep algorithm

General protocol

- Each bead can be treated as a separate queue, with Poisson arrival process with intensity $\lambda_{\mathcal{B}} = \lambda \frac{|\mathcal{B}|}{|\mathcal{O}|}$
- The vehicle visits each bead with at a rate no smaller than $\mu_{\mathcal{B}} \approx (\text{single sweep path length})^{-1}$
- The system time is no greater than the system time for the corresponding M/D/1 queue: $\overline{T}^* \leq \frac{1}{\mu_{\mathcal{B}}} \left(1 + \frac{1}{2} \frac{\lambda_{\mathcal{B}}}{\mu_{\mathcal{B}} - \lambda_{\mathcal{B}}}\right)$
- Optimize over ℓ

Example: Dubins vehicle

- $\lambda_{\mathcal{B}} = \frac{\ell^3 \lambda}{16\rho|\mathcal{Q}|}; \ \mu_{\mathcal{B}} \geq \frac{\ell^2 m}{16\rho|\mathcal{Q}|} \left(1 + \frac{7}{3}\pi \frac{\rho}{\sqrt{|\mathcal{Q}|}}\right)^{-1}$
- $\limsup_{\frac{\lambda}{m} \to +\infty} \overline{T}^* \frac{m^3}{\lambda^2} \le 71 \rho |\mathcal{Q}| \left(1 + \frac{7}{3} \pi \frac{\rho}{\sqrt{|\mathcal{Q}|}}\right)^3$

Analysis of the multiple sweep algorithm

General protocol

- Each bead can be treated as a separate queue, with Poisson arrival process with intensity $\lambda_{\mathcal{B}} = \lambda \frac{|\mathcal{B}|}{|\mathcal{O}|}$
- The vehicle visits each bead with at a rate no smaller than $\mu_{\mathcal{B}} \approx (\text{single sweep path length})^{-1}$
- The system time is no greater than the system time for the corresponding M/D/1 queue: $\overline{T}^* \leq \frac{1}{\mu_{\mathcal{B}}} \left(1 + \frac{1}{2} \frac{\lambda_{\mathcal{B}}}{\mu_{\mathcal{B}} - \lambda_{\mathcal{B}}}\right)$
- Optimize over ℓ

•
$$\lambda_{\mathcal{B}} = \frac{\ell^3 \lambda}{16\rho|\mathcal{Q}|}; \ \mu_{\mathcal{B}} \ge \frac{\ell^2 m}{16\rho|\mathcal{Q}|} \left(1 + \frac{7}{3}\pi \frac{\rho}{\sqrt{|\mathcal{Q}|}}\right)^{-1}$$

Outline of the lecture

- 4 The light load case

The light load case

• The target generation rate is very small: $\lambda/m \rightarrow 0^+$

In such case:

- Almost surely all vehicles will have enough time to return to some "loitering station" between task completion/generation times
- The problem is reduced to the choice of the loitering stations that minimizes the system time

Dynamic Vehicle Routing (Lecture 7/8) 29jun10 @ Baltimore, ACC

Dynamic Vehicle Routing (Lecture 7/8)

A simple lower bound

- The length of shortest feasible path from a vehicle positioned at $p \in \mathbb{R}^2$ to an arbitrary point $q \in \mathcal{Q}$ is lower bounded by ||q - p||
- A simple lower bound on \overline{T}^* is obtained by relaxing differential constraints
- $\overline{T}^* \geq \mathcal{H}_m^*(\mathcal{Q})$
- $\mathcal{H}_m^*(\mathcal{Q}) = \Theta\left(\frac{1}{\sqrt{m}}\right)$

The light load case

• The target generation rate is very small: $\lambda/m \rightarrow 0^+$

In such case:

- Almost surely all vehicles will have enough time to return to some "loitering station" between task completion/generation times
- The problem is reduced to the choice of the loitering stations that minimizes the system time

Introducing differential constraints

- Novel challenges:
 - Vehicles possibly cannot stop (e.g., Dubins vehicle, Reeds-Shepp car)
 - Strategies are more complex than defining a loitering "point"
- How many of the results from the Euclidean case carry over to this case?

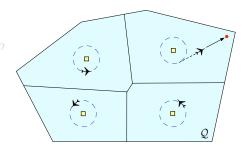

The Median Circling (MC) Policy

Assign "virtual" generators to each agent. All agents do the following, in parallel (possibly asynchronously):

- Update the generator position according to a gradient descent law.
- Service targets in own region, returning to a "loitering circle" of radius 2.91ρ centered on their generator position when done

$$\lim_{\lambda/m\to 0^+} T_{\mathrm{MC}} \leq \mathcal{H}_m^*(\mathcal{Q}) + 3.76$$

$$\lim_{\mathcal{H}_m^* o +\infty, \lambda/m o 0^+} rac{T_{ ext{MC}}}{\overline{T}^*} = 1$$

The Median Circling (MC) Policy

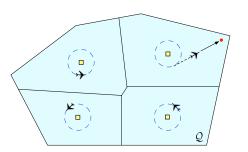

Assign "virtual" generators to each agent. All agents do the following, in parallel (possibly asynchronously):

- Update the generator position according to a gradient descent law.
- Service targets in own region, returning to a "loitering circle" of radius 2.91ρ centered on their generator position when done
- We have

$$\lim_{\lambda/m\to 0^+} T_{\mathrm{MC}} \leq \mathcal{H}_m^*(\mathcal{Q}) + 3.76\rho$$

Furthermore,

$$\lim_{\mathcal{H}_m^* o +\infty, \lambda/m o 0^+} rac{T_{ ext{MC}}}{\overline{T}^*} = 1.$$

Tighter lower bound using differential constraints

General protocol

- Consider a "frozen moment in time"
- Consider the "modified Voronoi" diagram of the vehicles.
- Relaxation: approximate vehicle Voronoi region by their reachable sets
- Optimize over the vehicle configurations

Example: Dubins vehicle For $m \ge m_{\rm crit}$, $\overline{T}^* \ge \frac{k_1(|\mathcal{Q}|, \rho)}{m^{1/3}}$

Tighter lower bound using differential constraints

General protocol

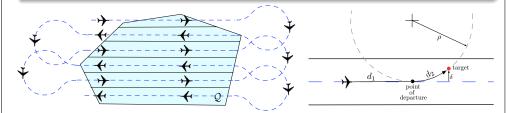

• Consider a "frozen moment in time"

Illustration of the MC policy

- Consider the "modified Voronoi" diagram of the vehicles.
- Relaxation: approximate vehicle Voronoi region by their reachable sets
- Optimize over the vehicle configurations

The Strip Loitering (SL) policy

- Divide the environment $\mathcal Q$ into strips of width $\min\left\{\frac{k_2(\mathcal Q,\rho)}{m^{2/3}},2\rho\right\}$
- Design a closed loitering path that bisects the strips. All vehicles move along this path, equally spaced, with dynamic regions of responsibility.
- Each vehicle services targets in own region, returning to the "nominal" position on the loitering path.

 $\lim_{m\to+\infty} T_{\mathrm{SL}} m^{1/3} \le k_3(\mathcal{Q}, \rho)$, and $\lim_{m\to+\infty} \frac{T_{\mathrm{SL}}}{\overline{z}^*} \le k_4(\mathcal{Q}, \rho)$.

Illustration of the SL policy

The Strip Loitering (SL) policy

- Divide the environment $\mathcal Q$ into strips of width $\min\left\{\frac{k_2(\mathcal Q,\rho)}{m^{2/3}},2\rho\right\}$
- Design a closed loitering path that bisects the strips. All vehicles move along this path, equally spaced, with dynamic regions of responsibility.
- Each vehicle services targets in own region, returning to the "nominal" position on the loitering path.

 $\lim_{m \to +\infty} T_{\operatorname{SL}} m^{1/3} \leq k_3(\mathcal{Q}, \rho), \quad \text{and} \quad \lim_{m \to +\infty} \frac{T_{\operatorname{SL}}}{\overline{\tau}^*} \leq k_4(\mathcal{Q}, \rho).$

Outline of the lecture

- Models of vehicles with differential constraints
- 2 Traveling salesperson problems
- 3 The heavy load case
- 4 The light load case
- 5 Phase transition in the light load

Phase transition in the light load

- We have two policies: Median Circling (MC), and Strip Loitering (SL). Which is better?
- Define the non-holonomic density $d_{\rho} = \frac{\rho^2 m}{|Q|}$.
 - ullet MC is optimal when $d_
 ho o 0$,
 - SL is within a constant factor of the optimal as $d_{
 ho} o +\infty$.
- phase transition: the optimal organization changes from territorial

• We have two policies: Median Circling (MC), and Strip Loitering (SL). Which is better?

- Define the non-holonomic density $d_{\rho} = \frac{\rho^2 m}{|Q|}$
 - MC is optimal when $d_{
 ho}
 ightarrow 0$,

Phase transition in the light load

- SL is within a constant factor of the optimal as $d_{\rho} \to +\infty$.
- phase transition: the optimal organization changes from territorial (MC) to gregarious (SL) depending on the non-holonomic density of the agents.

- Dynamic Team Forming
- 2 Three Policies
 - Complete Team
 - Task-Specific Team Policy
 - Scheduled Task-Specific Team Policy
- Analysis of Policies
 - Throughput vs System Time
 - Comparison of Results

Motivation for Team Forming

- Group of vehicles monitoring a region
- Several different sensing modalities:
 - electro-optical,
 - infra-red,
 - synthetic aperture radar,
 - foliage penetrating radar,
- Each event requires a subset of sensing modalities
- Equip each vehicle with a single sensing modality
- Form appropriate team to properly assess each event

How do we create teams in real-time to observe each event (service each request)?

Lecture outline

- Dynamic Team Forming

FB, EF, MP, KS, SLS (UCSB, MIT)

Dynamic Vehicle Routing (Lecture 8/8)

Dynamic Team Forming

Set of services $\{r_1, \ldots, r_k\}$.

Vehicle properties:

- k different vehicle types.
- Vehicle type $j \in \{1, ..., k\}$, can provide only service r_i .

Task (demand) model:

- Poisson and Uniform arrivals
- Each task requires a subset of services in $\{r_1, \ldots, r_k\}$.
- \bullet $\mathcal K$ different types of tasks
- Tasks of type α arrive at rate λ_{α}
- Task completed when required vehicles simultaneously spend on-site service time at location.

S. L. Smith and F. Bullo. The dynamic team forming problem: Throughput and delay for unbiased policies. Systems & Control Letters, 58(10-11):709-715, 2009

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 8/8)

29jun10 @ Baltimore, ACC

Load Factor and Stability

- $R_{\alpha} \in \{0,1\}^k$ is zero-one column vector recording services required for task-type α .
- on-site service for task-type α is \overline{s}_{α}
- m_i vehicles provide service r_i .

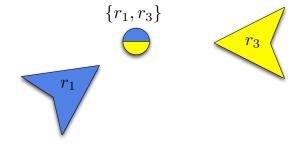

Necessary stability condition:

$$\begin{bmatrix} R_1 & \cdots & R_{\mathcal{K}} \end{bmatrix} \begin{bmatrix} \lambda_1 \bar{s}_1 \\ \vdots \\ \lambda_{\mathcal{K}} \bar{s}_{\mathcal{K}} \end{bmatrix} < \begin{bmatrix} m_1 \\ \vdots \\ m_k \end{bmatrix}$$

Load factor is now a vector

Example of Team Forming

- k = 4 different services, $\{r_1, r_2, r_3, r_4\}$.
- m = 8 vehicles, two of each type: $m_i = 2$ for $j \in \{1, 2, 3, 4\}$.
- $\mathcal{K} = 6$ task types, $\{r_1\}, \{r_2\}, \{r_3\}, \{r_4\}, \{r_1, r_3\}, \{r_2, r_4\}.$

Task type $\alpha = \{r_1, r_3\}$ has on-site service \bar{s}_{α} , arrival rate λ_{α} , and

$$R_{\alpha} = [1 \ 0 \ 1 \ 0]^{\top}.$$

Lecture outline

- 2 Three Policies
 - Complete Team
 - Task-Specific Team Policy
 - Scheduled Task-Specific Team Policy

Dynamic Vehicle Routing (Lecture 8/8)

and the optimization: $\inf_{\pi} \overline{T}_{\pi}$.

For a policy π :

Dynamic Vehicle Routing (Lecture 8/8) 29jun10 @ Baltimore, ACC

 $\overline{T}_{\pi,1} = \overline{T}_{\pi,2} = \cdots = \overline{T}_{\pi,K} =: \overline{T}_{\pi}$

• Optimization space similar to priority queues, but with teaming

Policy 1: Complete Team Policy

Complete Team Policy

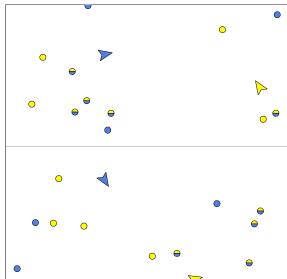

- 1: Form $\min\{m_1, \dots m_k\}$ teams of k vehicles, each team contains one vehicle of each type.
- 2: Have each team meet and move as a single entity.
- 3: In each region run UTSP policy (from Lecture 3).

Can also use Divide & Conquer policy for each team

Task-Type Unbiased Policies

• System time of each task-type \overline{T}_{π} , $1, \dots, \overline{T}_{\pi, \mathcal{K}}$ ullet Feasible set of system times are subset of $\mathbb{R}^{\mathcal{K}}$

To simplify, consider task-type unbiased policies

Policy 1: Complete Team Policy

- Two services y, b
- 3 task-types *y*, *b*, {*y*, *b*}.
- 4 vehicles
 - 2 yellow
 - 2 blue

Policy 2: Task-specific Team Policy

- m_i vehicles provide service r_i .
- r_j appears in $e_i^{\top}[R_1 \cdots R_{\mathcal{K}}]\mathbf{1}_{\mathcal{K}}$ task types.
- If $m_i \geq e_i^{\top}[R_1 \cdots R_{\mathcal{K}}]\mathbf{1}_{\mathcal{K}} \Rightarrow$ enough vehicles of type j to create dedicated team for each task type.
- Create m_{TST} teams, where:

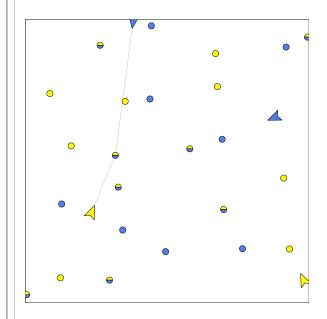

$$m_{ ext{TST}} := \left[\min_{j} \left\{ \frac{m_{j}}{e_{j}^{T} R \mathbf{1}_{\mathcal{K}}} \right\} \right]$$

Task-Specific Team Policy

- 1: For each of the ${\cal K}$ task types, create $m_{\scriptscriptstyle {
 m TST}}$ teams of vehicles.
- 2: Service each task by one of its m_{TST} corresponding teams, according to the UTSP policy.

Dynamic Vehicle Routing (Lecture 8/8) 29jun10 @ Baltimore, ACC

Policy 2: Task-Specific Team Policy

- task types: $\{y\},\{b\},\{y,b\}$
- two vehicles of each type
- y, b each appear in two task-types

$$m_{\scriptscriptstyle \mathrm{TST}}=1$$

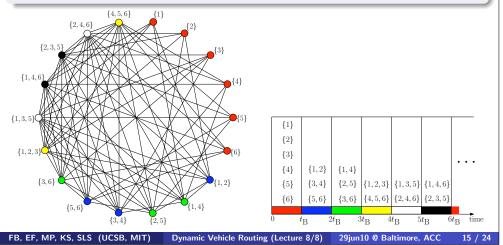

Dynamic Vehicle Routing (Lecture 8/8)

Policy 3: Preliminary Result

Definition (Service schedule)

A partition of task types into *L* time slots, such that:

- each type appears in exactly one time slot, and
- task types in each time slot are pairwise disjoint.

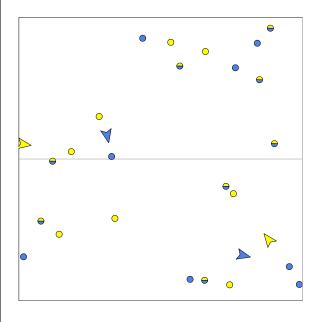

Policy 3: Scheduled Task-Specific Team Policy

Scheduled Task-specific team policy

Partition Q into $min_i\{m_i\}$ regions and assign one robot of each type to each region.

- 1: In each region form a queue for each task type.
- 2: For each time slot in the schedule:
 - ① Divide robots into teams to form required task types.
 - 2 For each team, service corresponding queue with TSP tour.

Policy 3: Scheduled Task-Specific Team Policy

Service schedule:

- two time slots L=2
- slot one: $\{y\}, \{b\}$
- slot two: {*y*, *b*}

Dynamic Vehicle Routing (Lecture 8/8)

Dynamic Vehicle Routing (Lecture 8/8)

Assumptions for Analysis

Assumptions:

- $\mathbf{0}$ $m_i = m/k$ for each vehicle type i.
- 2 $\lambda_{\alpha} = \lambda/\mathcal{K}$ for each task-type α .
- 3 on-site service has mean \bar{s} and is upper bounded by s_{max} .
- $p\mathcal{K}$ of the \mathcal{K} task-types require service r_i , where $p \in [1/k, 1]$.
- With assumptions, necessary stability condition becomes

$$\frac{\lambda}{m} < \frac{1}{nk\bar{s}}$$
.

• Define per-vehicle throughput as $B_m := \lambda/m$.

Lecture outline

Analysis of Policies

 Throughput vs System Time Comparison of Results

Throughput vs System Time Profile

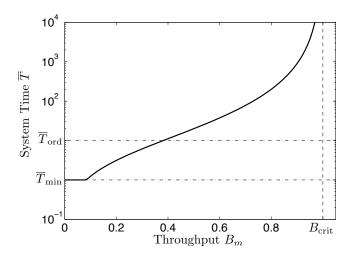

$$B_m \mapsto egin{cases} \max\left\{\overline{T}_{\min}, rac{\overline{T}_{\mathrm{ord}}(B_m/B_{\mathrm{crit}})}{(1-B_m/B_{\mathrm{crit}})^2}
ight\}, & ext{if } B_m < B_{\mathrm{crit}}, \ +\infty, & ext{if } B_m \geq B_{\mathrm{crit}}. \end{cases}$$

- \overline{T}_{min} = minimum achievable system time for positive throughput.
- $B_{crit} = maximum$ achievable throughput (or capacity).
- \overline{T}_{ord} = system time at a constant fraction of capacity $(3-\sqrt{5})/2 \approx 38\%$ of capacity $B_{\rm crit}$.

Example (Single vehicle DVR)

$$\begin{split} &B_{\text{crit}} = 1/\overline{s} \\ &\overline{T}_{\text{min}} = \mathbb{E}_{\varphi}[\|X - p^*\|]/v + \overline{s} \\ &\overline{T}_{\text{ord}} \approx C(\int_{O} \varphi^{1/2}(x) dx)^2/v^2 \end{split} \qquad \text{(light load)}$$

Throughput vs System Time Profile

Dynamic Vehicle Routing (Lecture 8/8)

29jun10 @ Baltimore, ACC

System Time for each Policy

	\overline{T}_{min}	\overline{T}_{ord}	$B_{\rm crit}$
Lower bound $(\overline{\mathcal{T}}^*)$	\sqrt{k}	k	$\frac{1}{pk\bar{s}}$
Complete Team	\sqrt{k}	k	$\frac{1}{k\bar{s}}$
Task-Specific	$\sqrt{pk\mathcal{K}}$	pkK	$\frac{1}{pk\bar{s}}$
Scheduled Task-Specific	$L\sqrt{k}$	Lk	$\frac{\mathcal{K}}{s_{max}Lk}$

where $L \in [p\mathcal{K}, \mathcal{K}]$

Best policies for different scenarios:

- If throughput is low, then use complete team
- If p is close to 1, then use complete team
- If p is close to 1/k, then for best capacity use
 - Task-Specific if enough vehicles
 - Scheduled Task-Specific otherwise

FB, EF, MP, KS, SLS (UCSB, MIT) Dynamic Vehicle Routing (Lecture 8/8)

29jun10 @ Baltimore, ACC

Lecture outline

- Dynamic Team Forming
- 2 Three Policies
 - Complete Team
 - Task-Specific Team Policy
 - Scheduled Task-Specific Team Policy
- Analysis of Policies
 - Throughput vs System Time
 - Comparison of Results

Workshop Structure and Schedule

8:00-8:30am	Coffee Break	
8:30-9:00am	Lecture #1:	Intro to dynamic vehicle routing
9:05-9:50am	Lecture #2:	Prelims: graphs, TSPs and queues
9:55-10:40am	Lecture #3:	The single-vehicle DVR problem
10:40-11:00am	Break	
11:00-11:45pm	Lecture #4:	The multi-vehicle DVR problem
11:45-1:10pm	Lunch Break	
1:10-2:10pm	Lecture #5:	Extensions to vehicle networks
2:15-3:00pm	Lecture #6:	Extensions to different demand models
3:00-3:20pm	Coffee Break	
3:20-4:20pm	Lecture #7:	Extensions to different vehicle models
4:25-4:40pm	Lecture #8:	Extensions to different task models
4:45-5:00pm		Final open-floor discussion
